fibrils corresponds to 12.5 Å, which comes very close to the lattice constant to dry collagen. It is interesting to note that the orientation of the proton of the  $\gamma$ -hydroxyl group with respect to the hydroxyproline ring atoms in the above structure is very similar to that reported from the neutron diffraction studies on 4-hydroxyl-L-proline<sup>2</sup>. In fact, it is also possible to have the hydrogen bond from the Hyp OH to O<sub>3</sub> of a neighbouring microfibril through the intermediary of a water molecule. If this is made reasonably good with hydrogen bond lengths of the order of 2.75 Å, then the separation between the neighbouring microfibrils comes to 14 Å. This roughly corresponds to the intermicrofibrillar distance in collagen at normal humidities.

Thus, we see that Hyp can serve a double purpose in collagen—(a) it can form hydrogen bonds linking neighbouring peptide chains in a single triple helix and (b) it can also form hydrogen bonds with a different triple helix to link the two together. Thus, without ever forming a covalent linkage, hydroxyproline can serve a very important purpose in stabilizing the collagen structure. It may be mentioned that two recent studies have experimentally verified that the melting temperature,  $T_m$ , of collagen fibres is about 15° higher when the prolines in position 3 in the peptide chain are all hydroxylated, than when they are not hydroxylated<sup>3,4</sup>. In the work by Berg and Prockop<sup>3</sup>, the  $T_m$  was measured directly from optical rotation studies and

FIG. 2. The hydrogen bond scheme linking O $\gamma$ H $\gamma$  of one microfibril in position 3 with O<sub>3</sub> of the next microfibril is shown for a central triple helix along with the three neighbouring microfibrils in hexagonal directions. It is to be noted that this linkage can be continued to form a good hexagonal lattice for the structure.

was shown to be appreciably larger for the hydroxylated form of collagen than the unhydroxylated form from the same source. In the latter studies by Jimenez *et al.*<sup>4</sup>, the thermal stability of unhydroxylated collagen relative to hydroxylated collagen was investigated using pepsin digestion at various temperatures as an enzymatic probe of conformation. Their results also indicate that the unhydroxylated molecules have a denaturation temperature between 20° and 25°, while the hydroxylated molecules are stable beyond 35°. These studies can be taken to be very good evidence in support of the theoretical ideas put forward from our laboratory regarding the role played by hydroxyproline in the stability of the collagen molecule.

## AMPEROMETRIC, POTENTIOMETRIC AND MAGNETIC STUDIES OF SOME RARE EARTH KOJATES

R. C. AGARWALA AND S. P. GUPTA

Department of Chemistry, D.N. College, Meerut 250002

### ABSTRACT

The reactions of the rare earth elements ( $\text{La}^{+3}$ ,  $\text{Ce}^{+3}$ ,  $\text{Pr}^{+3}$ ,  $\text{Nd}^{+3}$ ,  $\text{Sm}^{+3}$  and  $\text{Gd}^{+3}$ ) with kojic acid have been studied by employing amperometric and potentiometric titrations. The results of these titrations reveal 1:3 (metal:ligand) stoichiometry for the complexes. The experimental magnetic moments are in agreement with those reported for typical lanthanide sulphates and other compounds, indicating that metal ion in these chelates acts as a free ion, as far as the *f*-electrons are concerned.

### INTRODUCTION

**R**ARE earth complexes of kojic acid of the general composition  $[\text{M}(\text{C}_6\text{H}_5\text{O}_4)_3(\text{H}_2\text{O})_2]$  (where  $\text{M} = \text{La}^{+3}$ ,  $\text{Ce}^{+3}$ ,  $\text{Pr}^{+3}$ ,  $\text{Nd}^{+3}$ ,  $\text{Sm}^{+3}$ ,  $\text{Gd}^{+3}$ ,  $\text{Dy}^{+3}$ ,  $\text{Ho}^{+3}$  and  $\text{Y}^{+3}$ ) were prepared recently by us<sup>1-3</sup> and characterised. Analytical data and IR spectra of complexes show kojic acid acting as bidentate ligand and two water molecules are also present in the coordination sphere. In this communication the reactions of rare earth elements ( $\text{La}^{+3}$ ,  $\text{Ce}^{+3}$ ,  $\text{Pr}^{+3}$ ,  $\text{Nd}^{+3}$ ,  $\text{Sm}^{+3}$  and  $\text{Gd}^{+3}$ ) have been studied by employing amperometric and potentiometric titrations. Magnetic susceptibility data on the complexes are also reported in this paper.

### MATERIALS AND METHODS

All chemicals were of BDH (AR) quality. Elico model LI-10 pH meter, in conjunction with a glass electrode and a SCE, was used for potentiometric titrations conducted at 30°C. Amperometric and magnetic measurements were made as reported in the earlier communication<sup>2</sup>.

### RESULTS AND DISCUSSION

**Amperometric titrations.**—The amperometric titrations, both direct and reverse, were carried out, using 2 M sodium nitrate as supporting electrolyte and 0.2% gelatine solution as maximum suppressor, at the plateau of the rare earth ion (− 1.2 V) and the ligand (− 0.95 V) respectively.

From the results of these titrations it is indicated that the mole ratio in which the metal and the ligand combine to form the respective complex is 1 : 3.

**Potentiometric titrations.**—The titrations were carried out with the solutions containing the metal and the ligand in the ratios of 1:0, 1:1, 1:2 and 1:3 against 0.1 M NaOH.

The solution containing lanthanum nitrate alone exhibits only one inflexion point (Fig. 1, curve A), corresponding to the interaction of 3 moles of NaOH with 1 mole of lanthanum to give 1 mole of lanthanum hydroxide.

## ABSTRACT

It is shown that the previous report from the author's laboratory that hydroxyproline has a role in stabilizing collagen structure can be slightly modified to make it serve the purpose of not only leading to hydrogen bonds between two chains in the triple helix, but also in linking one triple helix with another. The modified scheme of hydrogen bonding is discussed and illustrated with diagrams.

IN a recent paper<sup>1</sup>, it was reported from our laboratory that hydroxyproline can play an important part in stabilizing the collagen structure by forming hydrogen bonds, with its hydroxyl group ( $O^{\gamma}H^{\gamma}$ ) playing a vital role in this linkage. The essence of the type of hydrogen-bonded linkages that was proposed is continued in the diamond shaped region shown in Fig. 1 of that paper. A more careful re-examination of this structure indicates that it would be possible for the hydroxyproline OH to be involved both in a hydrogen bond connecting two neighbouring chains (say A and B) in the triple helix, as well as to form a hydrogen bond with a neighbouring triple-helical protofibril. This arrangement of hydrogen bonds is shown in Fig. 1, where only the relevant atoms of chain A and B are shown in detail. It will be seen that the NH group ( $N_2H_2$ ), corresponding to the second residue in the sequence  $-Gly-X-Y-$  which occurs in collagen, forms a hydrogen bond with  $O_1$  of a neighbouring chain via the water molecule  $O^w$  ( $H_1^w, H_2^w$ ). Of the two protons in the water, one forms an almost straight hydrogen bond with  $O_1$  of chain A, while the second proton forms a hydrogen bond with the  $O_3^{\gamma}$  atom of chain A acting as a receptor for this bond (the standard nomenclature of referring to all atoms belonging to the same residue by the same subscript is adopted in this paper, which is slightly different from the earlier notation of denoting all atoms in the same peptide unit by the same subscript, which was adopted in Ref. 1). It will be seen, therefore, that the water molecule does not have any free proton available for external linkage in this model. For

the same reason, the water medium in the structure cannot easily disturb the water proton by forming a hydrogen bond via that atom.

FIG. 1. Diagram showing the hydrogen bonding arrangement in a protofibril of collagen involving the hydroxyproline OH group and a water molecule. The water molecule is linked differently with the Hyp  $O^{\gamma}$  from what was previously reported in Ref. 1. Here the water donates a proton to  $O^{\gamma}$  and the  $O^{\gamma}$  proton is the donor of the hydrogen bond linking the protofibril chain to a neighbouring protofibril. (The numbers denote the heights of the atoms concerned parallel to the fibre axis.)

What is more interesting is the fact that the proton  $H_3^{\gamma}$  of the hydroxyl group in residue 3 of chain A is now available for linking one protofibril with another. This is shown in Fig. 2 in which the linking hydrogen bond from Hyp for a central protofibril is shown with three other protofibrils in outline in the neighbourhood of this. The diagram shown corresponds to the case in which the hydrogen bond is direct between  $O_3^{\gamma}H_3^{\gamma}$  of the central protofibril and the  $O_3$  of the neighbouring protofibril. The distance between the two proto-

\* Contribution No. 53 from the Molecular Biophysics Unit, Indian Institute of Science, Bangalore-560 012, India.

fibrils corresponds to 12.5 Å, which comes very close to the lattice constant to dry collagen. It is interesting to note that the orientation of the proton of the  $\gamma$ -hydroxyl group with respect to the hydroxyproline ring atoms in the above structure is very similar to that reported from the neutron diffraction studies on 4-hydroxyl-L-proline<sup>2</sup>. In fact, it is also possible to have the hydrogen bond from the Hyp OH to  $O_{\beta}$  of a neighbouring protofibril through the intermediary of a water molecule. If this is made reasonably good with hydrogen bond lengths of the order of 2.75 Å, then the separation between the neighbouring protofibrils comes to 14 Å. This roughly corresponds to the interprotofibrillar distance in collagen at normal humidities.

Thus, we see that Hyp can serve a double purpose in collagen—(a) it can form hydrogen bonds linking neighbouring peptide chains in a single triple helix and (b) it can also form hydrogen bonds with a different triple helix to link the two together. Thus, without ever forming a covalent linkage, hydroxyproline can serve a very important purpose in stabilizing the collagen structure. It may be mentioned that two recent studies have experimentally verified that the melting temperature,  $T_m$ , of collagen fibres is about 15° higher when the prolines in position 3 in the peptide chain are all hydroxylated, than when they are not hydroxylated<sup>3,4</sup>. In the work by Berg and Prockop<sup>3</sup>, the  $T_m$  was measured directly from optical rotation studies and

FIG. 2. The hydrogen bond scheme linking  $O\gamma H\gamma$  of one protofibril in position 3 with  $O_{\beta}$  of the next protofibril is shown for a central triple helix along with the three neighbouring protofibrils in hexagonal directions. It is to be noted that this linkage can be continued to form a good hexagonal lattice for the structure.

On the addition of 1 mole of the ligand to the lanthanum nitrate solution, the pH of the solution is lowered (Fig. 1, curve B). This lowering of pH can be attributed to the release of protons during complex formation. The curve shows two inflexion points, one corresponding to 1 mole and the other to 3 moles of NaOH respectively. As the solution contains lanthanum and the ligand in 1:1 ratio, it is assumed that 1/3 of the metal reacts with the ligand to form 1:3 complex with the release of a proton which is neutralized by 1 mole of NaOH, while the remaining 2/3 of the metal is precipitated as hydroxide on the addition of another 2 moles of NaOH.

FIG. 1. pH-metric titration curves. A, 20 ml 0.005 M lanthanum nitrate + 30 ml  $H_2O$ ; B, 20 ml 0.005 M lanthanum nitrate + 5 ml 0.02 M kojic acid + 25 ml  $H_2O$ ; C, 20 ml 0.005 M lanthanum nitrate + 10 ml 0.02 M kojic acid + 20 ml  $H_2O$ ; D, 20 ml 0.005 M lanthanum nitrate + 15 ml 0.02 M kojic acid + 15 ml  $H_2O$ ; titrant, 0.1 M NaOH.

The titration of the solution containing metal and the ligand in 1:2 ratio (Fig. 1, curve C) shows two inflexion points, one corresponding to 2 moles and the other to 3 moles of NaOH respectively. This clearly indicates that at 2 equivalence the 2 protons were neutralized and other one equivalence of NaOH is required for the hydroxide formation.

Similarly with the solution containing metal and the ligand in 1:3 ratio (Fig. 1, curve D) shows only one inflexion point corresponding to 3 moles of NaOH, which are required to neutralize the 3 protons released during 1:3 complex formation.

Similar potentiometric behaviour was observed with the other rare earth ions ( $Ce^{+3}$ ,  $Pr^{+3}$ ,  $Nd^{+3}$ ,  $Sm^{+3}$  and  $Gd^{+3}$ ) showing thereby the existence of 1:3 complexes in these systems also.

**Magnetic measurements.**—Results of magnetic measurements at room temperature are presented in Table I. The effective magnetic moment has been calculated from corrected molar susceptibilities by Curie law.

$$\mu_{eff} = 2.84 \sqrt{\chi_M (\text{corr.})^T}$$

## AMPEROMETRIC, POTENTIOMETRIC AND MAGNETIC STUDIES OF SOME RARE EARTH KOJATES

R. C. AGARWALA AND S. P. GUPTA

Department of Chemistry, D.N. College, Meerut 250002

### ABSTRACT

The reactions of the rare earth elements ( $\text{La}^{+3}$ ,  $\text{Ce}^{+3}$ ,  $\text{Pr}^{+3}$ ,  $\text{Nd}^{+3}$ ,  $\text{Sm}^{+3}$  and  $\text{Gd}^{+3}$ ) with kojic acid have been studied by employing amperometric and potentiometric titrations. The results of these titrations reveal 1:3 (metal:ligand) stoichiometry for the complexes. The experimental magnetic moments are in agreement with those reported for typical lanthanide sulphates and other compounds, indicating that metal ion in these chelates acts as a free ion, as far as the *f*-electrons are concerned.

### INTRODUCTION

RARE earth complexes of kojic acid of the general composition  $[\text{M}(\text{C}_6\text{H}_7\text{O}_4)_3(\text{H}_2\text{O})_2]$  (where  $\text{M} = \text{La}^{+3}$ ,  $\text{Ce}^{+3}$ ,  $\text{Pr}^{+3}$ ,  $\text{Nd}^{+3}$ ,  $\text{Sm}^{+3}$ ,  $\text{Gd}^{+3}$ ,  $\text{Dy}^{+3}$ ,  $\text{Ho}^{+3}$  and  $\text{Y}^{+3}$ ) were prepared recently by us<sup>1,2</sup> and characterised. Analytical data and IR spectra of complexes show kojic acid acting as bidentate ligand and two water molecules are also present in the coordination sphere. In this communication the reactions of rare earth elements ( $\text{La}^{+3}$ ,  $\text{Ce}^{+3}$ ,  $\text{Pr}^{+3}$ ,  $\text{Nd}^{+3}$ ,  $\text{Sm}^{+3}$  and  $\text{Gd}^{+3}$ ) have been studied by employing amperometric and potentiometric titrations. Magnetic susceptibility data on the complexes are also reported in this paper.

### MATERIALS AND METHODS

All chemicals were of BDH (AR) quality. Elico model LI-10 pH meter, in conjunction with a glass electrode and a SCE, was used for potentiometric titrations conducted at 30° C. Amperometric and magnetic measurements were made as reported in the earlier communication<sup>2</sup>.

### RESULTS AND DISCUSSION

**Amperometric titrations.**—The amperometric titrations, both direct and reverse, were carried out, using 2 M sodium nitrate as supporting electrolyte and 0.2% gelatine solution as maximum suppressor, at the plateau of the rare earth ion (— 1.2 V) and the ligand (— 0.95 V) respectively.

From the results of these titrations it is indicated that the mole ratio in which the metal and the ligand combine to form the respective complex is 1:3.

**Potentiometric titrations.**—The titrations were carried out with the solutions containing the metal and the ligand in the ratios of 1:0, 1:1, 1:2 and 1:3 against 0.1 M NaOH.

The solution containing lanthanum nitrate alone exhibits only one inflexion point (Fig. 1, curve A), corresponding to the interaction of 3 moles of NaOH with 1 mole of lanthanum to give 1 mole of lanthanum hydroxide.

# OXIDATION OF CYSTEINE WITH CHLORAMINE-T AND DICHLORAMINE-T

N. M. MADE GOWDA, A. S. ANANDA MURTHY AND D. S. MAHADEVAPPA\*

Department of Post-graduate Studies and Research in Chemistry, University of Mysore,  
Manasa Gangolri, Mysore 570 006, India

THE oxidation of cysteine and other thiols<sup>1</sup> has been the subject of a number of investigations. The sulphhydryl group is generally oxidized to the corresponding disulphide, although instances of oxidation beyond the disulphide stage are known<sup>2,3</sup>. Kinetic investigations of the oxidation of thiols as a rule require rapid analytical techniques. Cysteine is an important amino acid and several analytical reagents<sup>4-11</sup> have been employed for assaying this compound by direct or through instrumental methods. In the present investigations, we have examined the behaviour of chloramine-T (CAT) and dichloramine-T (DCT) towards cysteine and we are reporting about some simple analytical methods devised for estimating the compound, with these reagents.

**Materials.**—L(+)-Cysteine (E. Merck) was purified by recrystallization from aqueous solution and was assayed to 95.5% by the iodimetric method<sup>4</sup>. The purity of the sample was checked by TLC and paper chromatographic methods, where it gave a single spot. An aqueous solution (~ 2 mg per ml) was prepared by dissolving the compound in water containing a few drops of dilute HCl. Other solutions of cysteine were prepared by dissolving the solid in appropriate buffers<sup>12</sup> and solvents.

CAT (E. Merck) was purified by the method of Morris *et al.*<sup>13</sup>. An approximately decinormal solution was prepared and standardized by the iodometric method. DCT was prepared and standardized by the method of Jacob and Nair<sup>14</sup>. Reagent grade materials were used in preparing solutions of other compounds. All solutions were prepared in triple distilled water.

Two methods were adopted for estimating the thiol.

(I) *Direct Titration Procedure*: Preliminary experiments showed that aqueous cysteine solutions can be directly titrated against CAT with starch-KI internal indicator in presence of dilute H<sub>2</sub>SO<sub>4</sub>. The overall concentration of H<sub>2</sub>SO<sub>4</sub> should be maintained at least at 0.2 N and higher acid concentrations did not affect the results. In the recommended procedure, aliquots of aqueous cysteine solution are taken in a titration flask. About 2 ml of starch-KI mixture and enough of 2 N H<sub>2</sub>SO<sub>4</sub> to make the overall concentration 0.2 N

are added. The solution is titrated against standard CAT solution to the appearance of a pale blue colour. The values are found to be reproducible.

A potentiometric titration between aqueous cysteine and CAT solutions was found to be unsuitable as no sharp potential break could be observed under the experimental conditions.

A direct titration of cysteine in glacial acetic acid solution against a 0.02192 N solution of DCT (in glacial acetic acid) was carried out potentiometrically and by visual end-point method as described for thoglycolic acid<sup>15</sup>. A potential break of about 100 mv was recorded for a 0.1 ml addition of titrant near the end-point.

Oxidation of the thiol involves a single electron change with both CAT and DCT, which can be stoichiometrically represented as:

where R' = HOOC.CH(NH<sub>2</sub>).CH<sub>2</sub> and R = p-CH<sub>3</sub>-C<sub>6</sub>H<sub>4</sub>SO<sub>2</sub>. The presence of disulphide (R<sub>2</sub> = 0.044) was detected by paper chromatography with butanol-acetic acid-water (4:1:5 v/v) as solvent and ninhydrin spray reagent (0.2% solution in butanol-water-acetic acid 95:4:0.5 v/v).

Some typical results of analyses are given in Table I. It can be seen that CAT and DCT can be used for a rapid and accurate assay of thiol.

The interference of some amino acids and related compounds in the estimation of cysteine was investigated. Lysine, leucine, glutamine, methionine and urea (~ 0.1 mmole) did not interfere in the estimation with CAT, while histidine, alanine, valine, serine, threonine, arginine, glycine, proline and thiourea interfered. Although a similar behaviour was noticed with DCT titrations, leucine and glutamine interfered while arginine, glycine, proline and urea had no effect.

(II) *Back Titration Procedure*: In preliminary experiments with CAT, known amounts of cysteine solution (~ 10 mg) prepared in the appropriate buffer were added to a known excess volume of CAT solution (~ 1.25 mmoles) in an iodine flask. The reaction mixture was set aside for various intervals of time, with occasional shaking. Then the excess CAT left unconsumed was determined

by back titration. A comparison of the extent of oxidation after 30 min. showed that there is a 10 electron change per mole of cysteine in buffer media of pH 1-3, which decreases with the increase in pH, i.e., 9.5 at pH 5, 8.8 at pH 7 and 6.3 in 0.1 N NaOH. The results were quite reproducible in the pH range 1-3 and the following procedure was therefore used for estimating the thiol. A solution of cysteine in pH 1 buffer (~2 mg/ml) was prepared. Aliquots of the solution were added to 50 ml of decinormal CAT solution in an iodine flask. The mixture was shaken occasionally and after 30 min. 10 ml of 2 N  $H_2SO_4$  and 10 ml of 20% KI were added and the liberated iodine was titrated against standard thiosulphate. The amount ( $x$  mg) of cysteine in the experimental solution is given by

$$x = 12.12 y (v_1 - v_2),$$

where  $y$  is the normality,  $v_1$  is the blank titration and  $v_2$  the volume of thiosulphate used to titrate the excess of CAT after oxidation of cysteine.

Stoichiometry of the above oxidation could probably be represented as follows:

Paper chromatography was used to identify the reaction products. Benzyl alcohol saturated with water was used as the solvent for detecting the sulphonamide ( $R_f = 0.905$ ) and 0.5% vanillin in 1% HCl solution in ethanol was the spray reagent. Attempts were made to detect the aldehydic amino acid with the amino acid solvent and spray reagent, employed for the disulphide. A spot corresponding to  $R_f = 0.091$  was observed and this probably can be taken as evidence for the compound.

Typical results of analyses are shown in Table I. The back titration procedure with DCT was unsatisfactory as the reaction was sluggish and showed only a 5-6 electron change per mole of cysteine (in glacial acetic acid solution) even after 40 minutes.

## LETTERS TO THE EDITOR

### VARIATION OF INTERNAL PRESSURE OF MERCURY WITH APPLIED PRESSURE AND TEMPERATURE

THE importance of the measurement of internal pressure of pure liquids, mixture of liquids and solutions has been stressed<sup>1-3</sup>. In this communication, the variation of the internal pressure of mercury, with applied pressure is studied, using the experimentally obtained data<sup>1</sup> for the computation.

*Method of Calculation of the Internal Pressure ( $\pi$ ).*

$$\pi = \left( \frac{\partial E}{\partial V} \right)_T - T \left( \frac{\partial S}{\partial V} \right)_T - p \quad (1)$$

From the thermodynamic equation of state.

$$\left( \frac{\partial S}{\partial V} \right)_T = \left( \frac{\partial p}{\partial T} \right)_V \quad (2)$$

From Maxwell's thermodynamic relations.

$$\left( \frac{\partial p}{\partial T} \right)_V = \left[ \frac{\partial p}{\partial V} \right]_T \left[ \frac{1}{V} \frac{\partial V}{\partial T} \right]_p \quad (3)$$

Therefore, equation (1) can be written as

$$\pi = \frac{T\alpha}{\beta_T} - p \quad (4)$$

where  $\alpha$  is the isobaric volume expansivity,  $\beta_T$  the isothermal compressibility,  $T$  the absolute temperature and  $p$  the pressure at which the system is examined.

$$\alpha = \frac{V_2 - V_1}{V_1(T_2 - T_1)} \quad (5)$$

where  $V_1$  and  $V_2$  are the volumes at  $T_1^\circ$  K and  $T_2^\circ$  K respectively, the volumes being measured at constant pressure.

$$\beta_T = \frac{V_2' - V_1'}{V_1'(P_2 - P_1)} \quad (6)$$

where  $V_1'$  and  $V_2'$  are the volumes at pressures  $P_1$  and  $P_2$  respectively when the temperature of the system is constant.

**Results and Discussion.**—The graph presented gives the variation of internal pressure with applied pressure at three different temperatures. Since it is linear with a negative slope, one can expect the internal pressure to pass through zero and become negative if the external pressure is increased. The internal pressure is due to intermolecular forces. As the applied pressure increases the repulsive forces between the molecules become dominant and this decreases the internal pressure. It is seen that the slope is almost the same at the temperatures at which the system is examined.

It is also observed that the internal pressure increases with the temperature when the pressure

is maintained constant. As the temperature is increased the distance between the conduction electrons in mercury increases which decreases the repulsive forces. Hence there is an increase in the internal pressure as the temperature is increased.

This study brings out the role of the repulsive forces in the internal pressure of liquids. Further study of the internal pressure in molten metals is in progress.

# ANALYSIS OF THE PHENOMENON OF MISCIBILITY IN A TERNARY SYSTEM: WATER-CARBON TETRACHLORIDE-METHANOL

TERNARY systems, in which a third component added to a mixture of two immiscible components brings about the disappearance of the phase boundary, resulting in a homogenous mixture, have been studied earlier by Suryanarayana and Somasundaram<sup>1,2</sup> from the point of view of dielectric contribution to miscibility. Recently we have studied the system water-carbon tetrachloride-methanol from the point of view of ultrasonics and other properties. We report herein an analysis of the phenomenon of miscibility.

*Experiments.*—All the components have been purified as described earlier<sup>3</sup>.

Equal volumes of water and carbon tetrachloride (100 ml each) were taken in a clean conical flask and kept in a thermostat maintained at  $35^{\circ}\text{C} \pm 0.1^{\circ}\text{C}$ . A known quantity of methanol was added, stirred well and allowed to attain equilibrium. Then the two layers were separated and the physico-chemical properties measured for each layer.

Ultrasonic velocity, density, dielectric constant and refractive index have been determined as given earlier<sup>3</sup>.

*Results and Discussion.*—It is expected normally that the added methanol will distribute between water and carbon tetrachloride. What is really happening is that as more and more methanol is added more carbon tetrachloride is being extracted into the top layer (Column 4 of Table II). An examination of the physico-chemical properties of the bottom layer indicates the presence of a single component (carbon tetrachloride), irrespective of the amount of methanol added. Bonner<sup>4</sup> made a similar observation on the system ether-water-ethanol. The added third component seems to modify the properties of only one layer and the binary mixture progressively extracts the second immiscible layer into it.

The authors are indebted to Dr. H. V. K. Udupa, Director, for the permission and encouragement given to do this piece of work and Dr. C. V. Suryanarayana, for helpful discussions. The authors from A. C. College of Engineering and

### EVALUATION OF AVERAGE L-SHELL FLUORESCENCE YIELDS INVOLVING PHOTO-EXCITATION

THE extensive data on average L-shell fluorescence yields ( $\bar{\omega}_L$ ) using direct fluorescent excitation for creating primary vacancies, that are available at present, dates back to 1934<sup>1</sup>. Since then more reliable data on L subshell photoelectric absorption, L subshell fluorescence yields and Coster-Kronig yields, needed for the evaluation of  $\bar{\omega}_L$ , have been made available in literature. We have evaluated  $\bar{\omega}_L$  for some elements in the range Z varying from 65 to 96 by using Scofield's<sup>2</sup> data of 1973 for the determination of primary vacancy distribution among L subshells involving photo-excitation at 20 keV (except for Cm) and 200 keV and most recent values of L subshells fluorescence yields and Coster-Kronig yields as recommended in a recent review article<sup>3</sup> of 1972. The values at 20 keV agree with those at 200 keV within errors involved because of the uncertainties in the experimental data on L subshell fluorescence yields and Coster-Kronig yields, showing that  $\bar{\omega}_L$  does not depend very much upon the energy of exciting radiations. Our values for  $\bar{\omega}_L$  at 20 keV are compared with those of Lay obtained in 1934 at 17.443 keV (Energy of Mo K $\alpha$  X-rays) in Table 1. It is seen that the values of Lay for all elements except W are at least 10% higher than the present values. Reliable data on the fluorescence yields are needed because of their many applications in a large variety of measure-

### ASCORBIC ACID OXIDASE IN THE RIPENING OF BANANAS

THE most significant factor responsible for the formation of dehydroascorbic acid in plant extract is the role of ascorbic acid oxidase. Thornton<sup>1</sup> reported that fruit contained an enzyme capable of destroying ascorbic acid. The present study reports the variation of ascorbic acid oxidase during the ripening of different varieties of banana, viz., Basrai, Harichal, Lalkel (variety of *Musa cavendishii*), Rajeli, Safed velchi (variety of *Musa paradisiaca*) at 13° C.

Basrai banana was obtained from Jalgaon District, Maharashtra State, while other varieties of bananas were obtained from Bassein Road, Bombay. In order to get banana bunches of uniform maturity, nearly 100 banana plants were tagged at the time of inflorescence emergence in a nearby banana plantation where uniform cultural practices were maintained throughout the growing season. From the above lots, two bunches each of uniform development were harvested at 100 days of growth after the inflorescence emergence. Harvesting period from inflorescence emergence was almost the same in all varieties. These bunches were immediately brought to the laboratory, separated into hands and upper hands of the bunches were stored in an

incubator at a temperature of 13° C. The ratio between pulp to skin weight was determined to assess the maturity of the fruits. In our previous experiment, 13° C was found to be more favourable temperature for ripening, and storage of bananas. Therefore the enzyme activity was carried out at this temperature. All the observations were made on detached banana fingers. Three fingers from each of the five banana hands were removed at a time and the average values are reported.

In order to find out the solubility of ascorbic acid oxidase, water, 3% sodium chloride, 30% alcohol and phosphate buffer (pH 7.0, 0.1 M) were tried and the enzyme activity was carried out by following the titrimetric method of Birch, Harris and Ray<sup>2</sup>. It was found that 3% sodium chloride was the best extracting solvent for ascorbic acid oxidase of the banana fruit pulp (Table I).

TABLE I  
*Extraction of ascorbic acid oxidase with different solvents*

| Solvent                        | Mg of ascorbic acid oxidised per 100 g wet weight basis in pulp | Ascorbic acid oxidase (units) |
|--------------------------------|---|-------------------------------|
| Water                          | 0.481   | 19                            |
| 30% alcohol                    | 0.672   | 27                            |
| 3% NaCl                        | 1.008   | 40                            |
| Phosphate buffer pH 7.0, 0.1 M | Nil   | Nil                           |

for the determination of ascorbic acid oxidase. Unit activity is defined as the percentage of oxidation of added ascorbic acid and taken to be the criteria of the amount of ascorbic acid oxidase present in tissues and each percentage oxidation represents one unit of the enzyme activity.

It can be seen from Table II that ascorbic acid oxidase activity during storage and ripening at 13° C increased upto yellow stage and then remained steady in the advanced progress of ripening. Fifty per cent ascorbic acid oxidase was observed to be left in an unoxidised form in green unripe stage, whereas in full ripe stage it varied from 35–40%. Babber<sup>3</sup> reported 50% units of ascorbic acid oxidase in bananas. In the present investigation ascorbic acid oxidase ranged in between 38–48% units on fresh weight basis. The highest activity was found in Harichal, Lalkel (48% units) bananas while lowest in Safed velchi banana (45% units). Basrai banana contained 40% units activity and was found to be higher than the other varieties at the initial green stage. There was not much difference in the per cent units activity of Basrai and Rajeli bananas at full stage.

Thanks are due to University Grants Commission for the award of financial assistance to one of us (DLP) for this research. Fresh bananas were supplied by Mr. K. H. Raut is thankfully acknowledged.

TABLE II  
*Enzymatic changes in ascorbic acid oxidase during the ripening of bananas*

| Storage period in days after harvesting |                           | 0<br>(initial stage) | 8     | 16    | 24    | 32       |

|   | do. oxidase (units)       | 39.04                | 41.53 | 43.63 | 45.31 |          |

10 g of banana pulp were homogenised in a Waring blender with 50 ml of 3% sodium chloride for 3–4 minutes. The homogenate was filtered through a double layer of muslin cloth and the residue was again re-extracted with 30 ml of the same solvent to ensure the complete extraction of the enzyme. The combined extracts were kept at 5° C for one hour and then centrifuged at 2,000 r.p.m. for 20 minutes and supernatant layer was made to volume, and used as an enzyme source

# MASS-SPECTRAL ANALYSIS OF PIGMENTS FROM *ARDISIA MACROCARPA* WALL

*Ardisia macrocarpa* Wall (Myrsinaceae), a high altitude plant, has been studied for the active principles and isolation of Rapanone (I) and a Leucoanthocyanidin 3, 4, 5, 7, 3', 4', 5'-heptahydroxy flavan has been reported<sup>1</sup>. The identity of the quinone as Rapanone (I) has been established by comparison of I.R., U.V. spectra of the samples of rapanone obtained from *Connorous monocarpus*<sup>2</sup>.

*Connorous monocarpus* yielded a mixture of quinones, whose mass-spectral analysis has been reported<sup>3</sup>. It has been shown to be a mixture of Homo-rapanone (III), Rapanone (I), Embelin (II), and Homo-embelin (IV). This prompted us to study the composition of the pigment obtained from *Ardisia macrocarpa* Wall to clarify whether the composition of the mixture is alike or different from that obtained from *Connorous monocarpus*.

Wood chippings of *Ardisia macrocarpa* Wall, obtained from Nepal, have been extracted and the quinone has been purified by thick-layer chromatography on silica gel using chloroform, methanol (9:1) as eluent. Rapanone which has been suspected to be a mixture has been analyzed mass-spectrometrically, while TLC showed no separation from the authentic sample. The observation of M, (M<sup>+</sup> + 1), and (M<sup>+</sup> + 2) peaks are in agreement with the data reported<sup>4,5</sup>.

- I R = C<sub>13</sub>H<sub>27</sub>  
II R = C<sub>11</sub>H<sub>23</sub>  
III R = C<sub>15</sub>H<sub>31</sub>  
IV R = C<sub>9</sub>H<sub>19</sub>

Rapanone is the major component of the quinone isolated both from *Connorous monocarpus* and *Ardisia macrocarpa* Wall. Mass-spectral data of *Connorous monocarpus* recorded a peak intensity of 90.2 for M<sup>+</sup> of Embelin, while that of pigment from *Ardisia macrocarpa* Wall recorded only 2.3 while that of M of rapanone being 100 in both cases. Mass-spectral data of sample under study indicated the presence of Homo-rapanone (III) (M<sup>+</sup>, 350 7.8%), Rapanone (I) (M<sup>+</sup>, 322 100%), Embelin (II) (M<sup>+</sup>, 294 2.3%) and the side chain fragments are C<sub>14</sub>H<sub>29</sub><sup>+</sup> (197), C<sub>12</sub>H<sub>25</sub><sup>+</sup> (169), C<sub>10</sub>H<sub>21</sub><sup>+</sup> (141). Mass-spectrum showed an intense

peak at M/e 153 (70.2%) which could be attributed to the residue (V).

The pigment isolated from *Ardisia macrocarpa* Wall showed the absence of Homo-embelin (IV), while it is found along with Rapanone (I), Embelin (II) and Homo-rapanone (III) in the sample isolated from *Connorous monocarpus*<sup>3</sup>.

The author is thankful to Professor Dr. Buchard Franck, Director, Organische Chemie Institut, Münster, West-Germany, for the Mass-spectrum.

## CHEMICAL EXAMINATION OF THE FATS FROM THE SEEDS OF *PHASEOLUS* SPECIES

LEGUMINOSAE is one of the families of plants, seed fats of which contain rarer or higher saturated acids<sup>1</sup>. *Phaseolus trilobus* (Mugani) and *Phaseolus aconitifolius* (Moth) are the species of Leguminosae family belonging to Papilionaceae sub-family. Their seeds come under pulses, and due to high protein content are used as food.

The fats from the seeds of *Phaseolus trilobus* and *Phaseolus aconitifolius* were extracted with 60–80° petroleum ether. The various chemical constants of the fats were determined by standard methods<sup>2</sup>. The physical and chemical constants are tabulated in Table I.

TABLE I  
Physical and chemical constants

| Constants            | <i>Phaseolus trilobus</i> | <i>Phaseolus aconitifolius</i> |
|----------------------|---------------------------|--------------------------------|
| Percentage of fat    | 5.2                       | 4.8                            |
| Specific gravity     | 0.912                     | 0.931                          |

\* Percentage by weight.

samples of fatty acids. Quantitative analysis of fatty acids was done by Urea-adduct Fractionation<sup>4,5</sup>. The results are compared with other *Phaseolus* species in Table II.

The major part of the fatty acid composition of the seed fat of *Phaseolus* species is unsaturated fatty acids. It varies from *Phaseolus vulgaris* (86%) to *Phaseolus trilobus* (54%). Linoleic and Linolenic acids are the main component acids of unsaturated acids of the other species but in the case of *Phaseolus trilobus*, Oleic acid (51.8%) is present as the main unsaturated part. Linolenic acid is absent and linoleic acid is in a very small quantity (1.8%) in *Phaseolus trilobus*. In *Phaseolus aconitifolius* all the three unsaturated acids are present in high percentages similar to *Phaseolus radiatus* but the linoleic acid is more than linolenic acid.

Palmitic acid is the main component fatty acid of saturated part in all *Phaseolus* species except in *Phaseolus trilobus*. In this case it is completely absent and large amounts of arachidic acid (16.4%) and lignoceric acid (21.4%) are present. Arachidic and lignoceric acids are in very small quantities in *Phaseolus mungo* and *Phaseolus radiatus*, and also not found in *Phaseolus aconitifolius*. *Phaseolus radiatus* contains 9.3% of behenic acid, but in other species it is absent or present in small quantities. A little higher percentage of stearic acid is observed in *Phaseolus mungo* and *Phaseolus trilobus*.

The small variations in fatty acid composition of the seed fats are possible by variation in ecological and seasonal conditions. But due to lack of data it is not possible to compare the compositions on the basis of ecological and seasonal conditions.

The unsaponifiable matter from the seed fats of *Phaseolus trilobus* (Mugani) and *Phaseolus aconitifolius* (Moth) gave the characteristic sterol reactions and identified as  $\beta$ -sitosterol.

My sincere thanks are due to Dr. R. K. Bajpai and Dr. Alok Singh, for their kind help.

#### SYNTHESIS OF 2-PHENYLINDOLE DERIVATIVES

IN connection with some synthetic work, we required 2-phenylindoles having alkyl and hydroxyl substituents in that ring. Whilst a few such derivatives are known, not many of them are described in literature. We report here four such new indole derivatives (Table I) conveniently prepared from the

TABLE I

phenyl-hydrazone of the corresponding hydroxy-dimethyl acetophenones by the application of the Fischer indole synthesis<sup>1</sup> using anhydrous zinc chloride at 170–80°. The yields of the indoles ranged between 15–20%. The colour reactions of these indoles with different reagents, their spectra and their adducts with sym-trinitrobenzene are given. All the four indoles did not give any colour with Ce (SO<sub>4</sub>)<sub>2</sub>. Satisfactory C, H, N analysis for the indoles as well as their adducts were obtained.

#### ON THE OCCURRENCE OF HALITE IN DIDWANA SALT LAKE AREA, RAJASTHAN

THE objective of this note is to report for the first time, the occurrence of Halite in Didwana salt lake area, situated at a short distance to the south of Didwana town (27° 24' : 74° 34') in the District of Nagour, Rajasthan. The implications of this occurrence on the Indian Geology are: (i) The cause of water salinity (surface and sub-surface), (ii) possibilities of occurrence of rock salt in other salt lake areas and (iii) a definite contribution towards the "Origin of salt in Salt lakes", particularly in Rajasthan.

The Didwana salt lake, producing the salt from subsurface brine for the last 500 years or so, consists of an oval-shaped depression lying in a valley, about 3½ miles in length and about 1½ miles in breadth, running south-west and north-east,

1. Robinson, B., *Chem. Revs.*, 1963, 63, 373 ;  
*Ibid.*, 1969, 69, 227.

bounded on the western side by an isolated spur mapped as Aravalli's by Heron<sup>1</sup>.

Although the Salt Expert Committee<sup>2</sup> constituted by the Government of India, recommended as far back as 1950, the detailed study of the strata upto the base rock, yet it was only during the last summer that, while digging a well in 'B' Mata Sector (27° 21' 40" : 74° 33' 50") a halite bed was encountered at a depth of 22' 6" from the surface. The halite bed was very hard in digging with the subsurface brine problem and thus could be deepened manually only upto 30' from the surface. The 7½' thick halite occurs here in the form of horizontal beds of variable thickness ranging from 3" to 10" and are intercalated with fine dark grey silt. These beds are overlain by a 5' 10" thick catcarious formation with upper part being lime 'Kankar' deposit which in turn is overlain by a 16' thick dark grey silt deposit, covered by a thin capping of loose sand at the top. In two more wells in the vicinity of the first well, the same formations at about the same depth were noticed. The location of these wells have been shown on the map given below:

#### GEOLOGICAL MAP AROUND DIDWANA

SHOWING LOCATION OF WELLS IN SALT LAKE

#### INDEX

- ☐ ALLUVIUM
- ☐ ARAVALLI QUARTZITE & SLATE

The halite revealed that the halite is pure, greyish white to white in colour, crystalline and waxy. Chemical analysis of one of the samples collected from the first well at depth of 26' from the surface shows a remarkable similarity with the sub-surface brine analysis and the salt analysis as given in Table I.

The similarity in chemical composition clearly indicates that the sub-surface brine in the Didwana salt lake, has resulted from this rock-salt dissolved

| Undetermined insoluble                             | 2.035                             | ..                         |
| Total  | 100.00                            | 100.00                     |

by subterranean water, which when raised up by the capillary action forms a layer of brine permeating the silt resting on the rock salt. In this context the author would certainly like to mention that the approximate ratio of Sodium Sulphate to Sodium Chloride in the sub-surface brine which is 1 : 3.5 remains same, irrespective of the seasons and fluctuations in sub-surface brine level. Secondly, the wells producing more brine, generally sink down by 5' or so, indicating about the inland sources of the brine in the salt lake, Didwana. Thus the aforesaid discovery contradicts the previously propounded theories of the salt being brought into the lake from outside sources, about the origin of the salt in Rajasthan salt lakes and in particular to the 'wind borne theory' proposed by Christae<sup>3</sup>.

Based on the physiography of the area, bedded nature of the halite deposit and the associated silt and 'Kankar' deposits, it is evident that this halite deposit is younger in contrast to the recently discovered halite occurrence in Bikaner area, in Rajasthan by Sinha, Singh *et al.*<sup>4</sup>. The author tentatively considers this halite as an evaporite deposit of Sub recent to Recent in origin.

The author expresses his thanks to Prof. G. L. Sharma, Head of the Chemistry Department, for his help in chemical analysis of the sample.

# **BARYTES IN VINDHYAN SEDIMENTS— A NEW FIND**

THE occurrence of barytes was not known so far from the Vindhyan rocks of India. During the course of recent work in the area near Rawat-Bhata (24° 56' : 75° 35'), (Rajasthan), the authors for the first time observed the occurrence of barytes as small veins, stringers, vug fillings and laminations in the Panna shales of upper Vindhyan age in the isolated hillock near Javra Kalan and in the adjoining areas. This new find is interesting both from the point of view of its academic interest and economic significance.

*General Geology* (Vindhyan Super group)

The geological sequence of rocks in the Rawat-Bhata area, between latitudes 24° 55'–25° 00' and longitudes 75° 35'–75° 40' (toposheet No. 45 P/9), is tabulated in Table I.

The barytes in vugs is mostly light pink to whitish in colour with interpenetrating crystals. The crystals are of bigger size in the core and smaller along the margins. The host rocks at the contact of the vugs, also show some disseminations of barytes. Besides barytes, small crystals of pyrite and marcassite are also noticed. A few specks of covellite (?), black tourmaline (?) and fluorite (?) are also present. Such vugs are circular to sub-spherical void in shape and vary in size upto 12 cm.

A prominent vein of about 30 cm width and 8 metres in length is exposed in N 60° E–S 60° W direction in Javra Kalan hillock. A few parallel thin veins and veinlets are also seen trending in the same direction. These veins do not appear to have much depth persistence. As regards the fine laminations of barytes, the occurrence is ubiquitous.

TABLE I

|               | Book succession  | Approx. exposed thickness in metres | Correction based on older nomenclature |
|---------------|--|-------------------------------------|--|
| Bhandar group | Sandstones with interbeds of shales  | 50–70                               | Lower Bhandar sandstones               |
|               | Greenish grey shales   | 25–40                               | Sameria shales (Coulson) <sup>1</sup>  |
|               | Purple and greenish laminated limestones   | 20–30                               | Sirbu shales (Heron)                   |
|               | Brown shales   | 20–30                               | Lower Bhandar limestones               |
| Rewa group    |  | Unconformity                        | Ganurgath shales                       |
|               | Arkosic sandstones   | 1–10                                | Upper Rewa sandstones                  |
|               | Greenish grey shales and siltstones  | 2–30                                | Jhiri shales                           |
|               | Massive sandstones, conglomeratic at the base  | 1–5                                 | Lower Rewa sandstones                  |
|               | Red to purple shales and siltstones with thin laminations, vugs and veins of Barytes | 20–30                               | Panna shales                           |
| Kaimur group  | Gluconitic sandstone, limestone and shales   | 4–10                                |  |
|               |  | Unconformity                        |  |
|               | Red to purple, light grey sandstones with a thin argillaceous band                   | 60–90                               | Kaimur series                          |
| Senri group   |  | Unconformity                        |  |
|               | Greenish grey shales   |                                     | Suket shales                           |
|               |  | Base is not seen                    |  |

Structurally, the rocks of the area are almost horizontal to gently undulating except near the contact beds of Kaimur, Rewa and Bhandar groups which show dips upto 20°–30°, particularly along the western limb of the regional Dipura anticline plunging 3–4° towards northwest.

*Mode of Occurrence of Barytes.*—The barytes observed in the Panna shales occur as vug fillings in the lower horizon of shales and calcareous siltstones (?) near Javra Khurd. The narrow veins and/or joint fillings, laminations and rosettes are noticed in the reddish-purple shales in the upper part of the Panna sequence in the isolated hillock near Javra Kalan.

Chemical analysis of one sample of barytes : BaO 62.71%, SO<sub>4</sub> 32.84%, CaO 0.28%, SrO 0.72%, Mg 600 ppm and Cu 25 ppm, while the host rocks shale contains BaO 8.15%, SO<sub>4</sub> 4.32%, CaO 14.0%, MgO 11.70% and Sr 350 ppm.

*Origin of Barytes.*—The natural abundance of barium in the earth's crust is known to be about 300–500 ppm. Its arrival in the upper crust is thought to be related with the volcanic activity or emplacement of igneous rocks and attended vein systems. In igneous rocks, the basalts contain as little as 100 ppm Ba, granites 700–800 ppm and syenites and potassic igneous rocks have as much as 3000–5000 ppm. Amongst the sedimentary rocks,

particular shales are known to have 500–1000 ppm. Ba<sup>2+3</sup>.

The barytes of sedimentary origin occur either as a continuous bed or lenticular and worm-like bodies or as nodules. The internal texture of the baryte nodules often displays a radiating pattern of crystals from a common centre. The central portion often shows a concentric ring type pattern with the finest material in the centre<sup>4</sup>.

In the light of above background information, and considering the evidences of igneous activity in the Vindhyan basin as a whole, it seems plausible to assume that the origin of the barytes in the present area might be related to some igneous activity as plutonic emplacement or as submarine volcanic emanations in the basin. Since the occurrence of barytes is restricted to the Panna shales horizon, it is obvious to think that the igneous activity, which has brought the barytes in sediments, must have occurred after the deposition of the lower Vindhyan rocks in the basin and such igneous source bodies are concealed under the thick pile of overlying sediments.

**Conclusion.**—The present find of barytes in Vindhyan sediments, besides opening up a new vista in search of economic bodies in the Vindhyan strata, has also afforded clues of igneous activity in the Vindhyan basin of Rajasthan, which was not known so far. It may be mentioned that the occurrence of baryte in Vindhyan rocks of Rawat-Bhata area is entirely a new find and the ideas put forward for its origin by the authors provide scope for locating more such barytes occurrences.

The authors are grateful to Shri S. Narayana-swami, Dy. Director General, G.S.I., Western Region, for his valuable suggestion and editing of the paper.

## SEXUAL DIMORPHISM IN THE CAT FISH *MYSTUS (MYSTUS) VITTATUS* (BLOCH)

STERBA<sup>1</sup> describing *Mystus vittatus* states 'Sex distinctions are not known'. Bhatt<sup>2</sup>, however, working on the biology of the fish, mentions about sexual dimorphism—'Sexual dimorphism in *Mystus vittatus* is of permanent nature and can be easily seen in the males in the form of a genital papilla. This papilla is a projection of the genital aperture and varies from 2 mm to almost 10 mm in length. The genital papilla is seen throughout the year and gets more enlarged during the spawning season.'

For the present study more than one thousand specimens were examined in the months of May and June. The fishes were collected from the local lakes and rivers. Their size ranged between 70 mm–120 mm for the males and 70 mm–145 mm for females. The male and the female ratio was found to be approximately 1:1.3.

While the males possess a well-developed genital papilla as reported by Bhatt<sup>2</sup> (Fig. 1) they also display in addition a spear-shaped thickening at the base of the caudal fin near the level of the lateral line and almost extending upto the fork (Fig. 1).

FIG. 1. Photograph of the posterior half of an adult *Mystus vittatus* showing the genital papilla and the thickening between 7th and 9th fin rays (arrows),  $\times 1.7$ .

FIG. 2. Photograph of the posterior half of a female *M. vittatus*,  $\times 1.5$ .

It lies between the seventh and the ninth fin rays embracing their basal part and more or less envelop-

ing the eighth fin ray. Males, measuring below 80 mm approximately do not show this thickening hence it may be taken as a secondary sexual character. The females do not possess any of the characters mentioned above for the males (Fig. 2). Thus, it is very easy to identify the sex of this species at the first sight. And also, the thickening stands as an indicator to know the maturity of the male fish.

#### A NOTE ON TUNA FISHERY AROUND AGATTI ISLAND (LAKSHADWEEP) IN RELATION TO HYDROGRAPHIC CONDITIONS LEADING TO THE PHENOMENON OF UPWELLING

HYDROGRAPHIC studies conducted by Rao and Jayaraman (1966) around Minicoy islands indicated the presence of upwelling during late November and suggested that this phenomenon may have considerable impact on the peak tuna catches in this region.

The present observations are based on meteorological, hydrographic and fishing data collected by the training-cum-fishing vessels 'Blue Fin' and 'Masterfisherman I' attached to the Central Institute of Fisheries Operatives. Both the vessels were on a 10 day cruise to Lakshadweep islands during the 2nd week of December (1973).

Being the only island in the group from where moderate to good fishing for skipjack tuna (*Katsuwonus pelamis*) was reported during the season, both meteorological and hydrographic data were collected from 5 fixed oceanographic stations around the Agatti island, side by side with pole and line fishing operations.

Large shoals of skipjack tuna were observed especially on the southern and south-western side of the island. The fishes caught by the pole and line fishing boats were more or less of the same size group (approximately 18" in length) and weighed on an average between 2 kg and 2.5 kg. The fishing was moderately good and on an average each pole and line fishing vessel could catch a minimum of around 100 numbers of tuna within a period of one hour. The catch per hour for the above-mentioned individual species of tuna worked out to approximately 250 kg especially of those boats which were fishing on the southern and south-western side of the island.

The prevailing surface currents were north-westerly to north-north-westerly and the velocity of the flow was moderately high. The surface water temperature varied between 28.0° C and 28.1° C and on an average the isothermal layer was found to extend to depths of 50 mtrs. to 55 mtrs. from where the thermocline was found to extend to depths of 90-95 mtrs. at more or less all the stations. The surface salinity varied between 34.799‰ and 35.028‰ with the maximum concentration of the shoals at regions of comparatively higher salinities.

It was observed that the surface currents which head towards the island on its southern tip diverge into two branches one on the eastern side and the other on the western side. The comparatively higher salinity values and low temperature values observed at the surface levels on the southern side of the island indicate the possibility of upwelled water in this area brought from sub-surface levels through the process of upwelling.

It is known that tuna gather around areas of upwelling and in areas where the thermocline is shallower (Nakagome, 1973). Studies conducted in the Caroline and Marshall islands have revealed that better catches of Big eye tuna was brought in during the season when the sea surface temperature was comparatively lower (Nakagome, 1958, 1965). Uda and Nakamura (1973) have observed that the region of maximum hook rate appears to be localised either in the marginal area, water boundaries or along oceanic fronts.

Thus the concentration of large shoals of tuna on the southern side of the island may perhaps indicate a possible relationship between the occurrence of tuna shoals and upwelling zones. It is worth mentioning in this context that in the year 1966 in the presence of diverging currents and the resulting upwelling a good fishery for skipjack tuna flourished around Minicoy island. It seems quite likely that the divergence zone which leads to a favourable environment is shifting from one area to another possibly depending on the velocity and

direction of the prevailing current system, geographical location of the islands, bottom topography of the atolls, etc. It may be possible that probable fishing grounds for skipjack tuna in the Lakshadweep area of the Arabian Sea could be predicted sufficiently in advance, by keeping a constant watch on the formation and shifting of divergence zones around the islands during the period September to April, the season for the skipjack tuna fishery. Further investigations in this line are worth taking up.

The authors wish to express their sincere thanks to Dr. A. V. S. Murthy, Fishery Scientist (Oceanography), Central Marine Fisheries Research Institute (ICAR), for the helpful discussions, Shri George Varghese, Director of Fisheries, Lakshadweep, for making available the facilities in the form of tuna pole and line fishing vessels and gear and to the skippers of the training vessels, Capt. K. Balan and Capt. R. Velayudhan and the crew for their sincere cooperation.

#### A NOTE ON THE CHANGES IN SOME QUALITATIVE CHARACTERS DURING THE LAST PHASE OF MATURATION OF INDIAN MUSTARD SEED (*BRASSICA JUNCEA*, COSS)

DURING the later stages of maturation of an oilseed plant several changes occur in the seed very rapidly. The seeds shed lot of moisture, accumulate more dry matter, rate of oil formation increases rapidly and other changes occur in the composition of oil. Simultaneous with oil formation the fat content (dry wt. basis) and fat out-turn per unit number of seeds first increases upto a point and then slightly comes down at the end of dead ripening stage<sup>1</sup>.

The other important constituents in the seeds are the fatty acids of the oil. Erucic acid (major acid in rapeseeds and mustards) did not usually become the major acid until 35 days after flowering in *Sinapis alba*<sup>2</sup>. In the earlier stages saturated acids

were high in percentage but came down gradually as the seeds matured. In the end erucic acid accounted for nearly 45% of the total acids.

A study was made with a variety of commonly cultivated Indian mustard (*B. juncea* Coss) var. Appressed Mutant to observe these changes during maturation.

**Experimental.**—Sample of seeds were collected from a crop of mustard var. Appressed Mutant starting from 75 days after sowing and at an interval of four days till 95th day. The pods were shattering type and, therefore, were harvested when just turned yellow. Moisture percentage was determined by drying the seeds in an oven at 120°C for 2 hours. Oil was extracted in Soxhlet's apparatus for 8 hours with petroleum ether B.P. 60–80°C., after crushing the seeds thoroughly in a mortar. Fatty acids were analysed in Gas Liquid Chromatograph. Methyl esters were prepared for this purpose by transmethylation with 14% BF<sub>3</sub>-Methanol<sup>3</sup>. The esters were analysed in a F and M model 700–12 analytical g.l.c., with a dual flame ionization detector and a 6' × 1/8" stainless steel column packed with 10% D.E.G.S. supported on Gas Chrome P (60–80, mesh). Operating conditions were oven temp. 180°C, chart speed 15 inch/hour and range 10<sup>4</sup>. The carrier gas was nitrogen. The area under a 'peak' was measured by the method of retention time × peak height<sup>4</sup> and the percentages were calculated by 'Area Normalization method'<sup>5</sup>. All the estimations were done with duplicate samples.

TABLE I  
Changes in chemical composition during maturation of mustard seeds

| Days after sowing | Moisture % | Oil % | Dry wt. of 100 seeds in mg | Oil out-turn/ 100 seeds (dry wt. basis in mg) |
|-------------------|------------|-------|----------------------------|---|
| 75                | 58.03      | 19.60 | 117.2                      | 54.73   |
| 79                | 57.78      | 20.39 | 136.0                      | 65.68   |
| 83                | 56.08      | 22.23 | 160.1                      | 81.03   |
| 87                | 52.67      | 23.04 | 169.7                      | 82.61   |
| 91                | 50.55      | 24.67 | 180.5                      | 90.05   |
| 95                | 32.35      | 27.18 | 208.2                      | 83.61   |

**Results and Discussion.**—Some of the quality factors have been presented in Table I. The moisture percentage came down steadily, but at the last stage the decrease was very rapid resulting in a lowering of 18%. The oil percentage on fresh weight basis increased steadily and it appears that there was a quicker synthesis of oil during the last week under study. Similar trend was observed in the case of seed weight. There was a 100% increase in weight in about 20 days. Weight of oil per unit number of seed increased till 91st day, then there was a sud-

den drop of 7 mg. A similar trend<sup>1</sup> was also observed in oil quantity during the last stage of maturation elsewhere. It is obvious from the data that the synthesis of oil and increase in dry matter both goes on at a faster rate during the last phase of maturity. At the same time there is rapid depletion of moisture from the seed. In this particular variety the moisture comes down to 12% after drying and threshing the crop, which incidentally increases the oil percentage to nearly 33–35%. This of course does not mean that any oil synthesis takes place in this period. It will be also obvious from the last column that actual percentage of oil (on dry wt. basis) comes down during the last four days, implying thereby, that synthesis either stops or slows down very considerably.

One of the quality aspects of the oil is the fatty acid composition. This is becoming an important consideration as more and more people are becoming conscious of it and also clinical studies are being undertaken to evaluate any harmful effect of the oil on human beings. In this study (Table II)

TABLE II

Fatty acid percentages by weight of eight major fatty acids in maturing mustard seeds

| Fatty acid | Days after sowing |       |       |       |       |       |
|------------|-------------------|-------|-------|-------|-------|-------|
|            | 75                | 79    | 83    | 87    | 91    | 95    |
| C 16 : 0   | 3.15              | 3.98  | 3.83  | 3.54  | 3.23  | 2.09  |
| C 18 : 0   | 2.41              | 2.54  | 1.87  | 1.89  | 1.46  | 1.13  |
| C 18 : 1   | 8.90              | 9.34  | 10.24 | 8.24  | 9.58  | 9.12  |
| C 18 : 2   | 15.80             | 15.92 | 15.50 | 13.98 | 14.96 | 13.71 |
| C 18 : 3   | 12.80             | 12.16 | 16.36 | 15.86 | 11.89 | 12.71 |
| C 20 : 1   | 6.18              | 6.04  | 8.40  | 7.93  | 6.53  | 5.40  |
| C 20 : 2   | 1.30              | 1.35  | 1.55  | 0.72  | 1.32  | 0.94  |
| C 22 : 1   | 49.46             | 48.69 | 42.25 | 47.84 | 51.03 | 54.10 |

the percentages of saturated fatty acids and C 18 : 2 (linoleic) came down gradually during maturation while among the unsaturates, C 18 : 1, C 18 : 3, C 20 : 1, and C 20 : 2 increased upto 83 days; then there was a gradual decrease. The erucic acid (C 22 : 1) showed an erratic trend. It increased from 87th day till 95th day. Before this period there was a gradual decrease. Similar type of observation has been made by others<sup>2</sup>. In the light of present theories of fatty acid biosynthesis, there is simultaneous desaturation from Oleic to higher homologues and a chain elongation process from Oleic to Eicosenoic and finally to Erucic<sup>3</sup>. The latter process seems to be more in evidence in this study, the desaturation process showing little impact on the synthesis pattern of the fatty acids. There could be of course a possibility that the chain elongation was a faster process thereby giving less

scope to the precursor to be desaturated at a very slow process to its higher homologues. These studies may help in understanding the quick changes that occur during maturation of an oilseed, specially in determining the optimum harvest stage from the quality point of view.

## CURRENT POSITION OF PHYSIOLOGIC RACES OF *PYRICULARIA ORYZAE* CAV. IN INDIA

THE first report on the occurrence of physiologic races in the fungal pathogen, *Pyricularia oryzae* Cav. in India was by Padmanabhan<sup>1</sup>. Padmanabhan *et al.*<sup>2</sup> reported the occurrence of thirty-one races of the pathogen. A report<sup>3</sup> from Central Rice Research Institute added one more race of the pathogen to the list.

The current contribution covers the present position of prevalence of races of *P. oryzae* in India for the period 1972 and 1973.

The isolates of the pathogen utilized in the study were obtained by isolation from blast specimens collected from Kerala, Tamil Nadu, Karnataka, Andhra Pradesh, Orissa, West Bengal, Assam, Bihar, Madhya Pradesh, Uttar Pradesh, Himachal Pradesh, Jammu and Kashmir, Rajasthan, Gujarat and Maharashtra. One hundred and eight isolates of *P. oryzae* were isolated and identified.

The international set of eight differential rice varieties, viz., Ramínad str. 3, Zenith, NP. 125, Usen, Duilar, Kanto-51, CI 8970(S) and Caloro were utilised for the experiment. The susceptible rice variety, Co. 13, was utilised as a check since the occurrence of an isolate of the race II (non-infective on the eight differentials but pathogenic on Co. 13) has been reported by Padmanabhan *et al.*<sup>2</sup>.

The method adopted for identification of races of the pathogen was the one described by Padmanabhan

*et al.*<sup>4</sup>. The classification of races of *P. oryzae* of Ling and Ou<sup>5</sup> was adopted.

The results are presented in Table I.

TABLE I  
Composition and distribution of races of *P. oryzae*

| Race  | Year |      |
|-------|------|------|
|       | 1972 | 1973 |
| IC-1  | 2    | Nil  |
| IC-17 | 46   | 60   |

The race IC-1 could be identified from the isolates belonging to Orissa and Rajasthan. The race IC-17 could be identified from amongst the isolates from all the states mentioned above. The variety Co. 13 proved susceptible to all the one hundred and eight isolates of *P. oryzae*.

The situation reveals that the isolates belonging to the IC group are more predominant and more stable than all other races. Padmanabhan *et al.*<sup>2</sup> reported that the most prevalent races in India were IC-3 followed by ID-1 (Atkins *et al.* classification<sup>6</sup>), i.e., IC-17, ID-1 (Ling and Ou classification)<sup>5</sup>. The reactions of the differential varieties to race IC-1 and IC-17 are presented in Table II.

TABLE II  
Reaction of differential varieties to race IC-1 and IC-17 of *P. oryzae*

| Variety | Raminad<br>str. 3 | Zenith | N.P. 125 | Usen | Dular | Kanto-51 | CI. 8970(S) | Caloro |
|---------|-------------------|--------|----------|------|-------|----------|-------------|--------|
| Race    |                   |        |          |      |       |          |             |        |
| IC-1    | R                 | R      | S        | S    | S     | S        | S           | S      |
| IC-17   | R                 | R      | S        | R    | S     | S        | S           | S      |

The difference between the reaction of the test isolates of the variety Usen, i.e., whether the infection manifested itself as a circular spot with central ashy zone and dark purplish brown margin classified as 'C' spot, or as a broadly spindle-shaped spot 'D' as described by Padmanabhan *et al.*<sup>4</sup> decides whether the variety behaved as resistant or susceptible.

Both 'C' and 'D' spots reveal central ashy zone, brown margin and sporulation. Besides, there are lesions which could be falling between 'C' and 'D' types of spots. Therefore it is proposed that the 'C' type spots may be classified as indicative of a susceptible reaction. Sometimes isolates of *P. oryzae* occurring in India produce a border-line reaction on the variety, Usen, which lies between resistance and susceptibility (C and D type spots). It is therefore necessary to replace the variety, 'Usen' with a short duration variety with a clear-cut reaction like, Co. 13.

Help received from scientists belonging to the Department of Agriculture of the different States of India and Universities in providing blast specimens is gratefully acknowledged. Help rendered by Sri N. K. Chyau Patnaik, Assistant Botanist, in maintaining the purity of the differentials and supply of seeds is also gratefully acknowledged. The authors are grateful to Dr. S. Y. Padmanabhan for his keen interest and encouragement.

## CYTOLOGY OF *PASPALUM SCROBICULATUM* LINN.

THE genus *Paspalum* Linn. consists of 350 species widely distributed in the tropics and subtropics of both the hemispheres<sup>1</sup>. In India this genus is represented by 14 species<sup>2</sup>. *Paspalum scrobiculatum* Linn. is an important minor millet chiefly cultivated in India. The grain is used for preparing pudding or porridge. The chromosome number has been reported to be  $2n = 40$  and  $n = 20$  in this species<sup>3,4</sup>. The karyotype and meiotic behaviour, however, have not been investigated. This communication deals with these aspects.

The seeds were obtained through the courtesy of Botanical Survey of India, Southern Circle, Coimbatore. For karyotype study the root tips were excised from the potted plants and pretreated with 0.002 molar 8-hydroxyquinoline for 3 hours. They were stained with Lillie's (1951)<sup>5</sup> Schiff's reagent. Spikes were fixed in Carnoy's fluid (6:3:1) and microsporocytes were stained with acetocarmine. The slides were made permanent using acetic acid-butanol series and mounted in euparal.

The present study confirms the earlier counts of  $2n = 40$  and  $n = 20$  chromosomes. The somatic chromosomes are shown in Fig. 1. They are medium sized. The difference between longest and shortest chromosome in the complement is very

small. Therefore they cannot be categorized into long, medium and short chromosomes. They form a gradual series. There are three types of chromosomes, a single satellited submedian pair with SAT on long arm, eight pairs of median chromosomes and eleven pairs of chromosomes with submedian centromere. The satellite is small and measures about 0.5 micron. The chromosome length ranges from 1.9 to 3.5 microns with an absolute length of 103.9 microns.

Figs. 1-4. Fig. 1. Somatic metaphase plate showing  $2n = 40$  chromosomes. Fig. 2. Metaphase I with 20 bivalents. Fig. 3. Diakinesis showing 18 bivalents and 1 quadrivalent ( $\uparrow$ ). Fig. 4. Metaphase I with 16 bivalents and 2 quadrivalents ( $\uparrow$ ). All Figs.  $\times 900$ .

The meiotic behaviour is studied in detail. Twenty bivalents are observed at diakinesis and metaphase I (Fig. 2). The bivalents are mostly ring shaped. However, approximately 10% of the PMC's contain 1-2 quadrivalents (Figs. 3-4). Anaphasic separation at first and second division is mostly normal. Sporadically 1-2 lagging chromosomes are found at anaphase I and II. The tetrad formation is regular.

From the available evidences<sup>6</sup> it appears that 10 is the basic chromosome number in *Paspalum*. Thus *P. scrobiculatum* with  $2n = 40$  chromosomes is a tetraploid. Regular 20 bivalent formation at meiosis indicates its allotetraploid nature. Occurrence of small percentage of quadrivalents possibly suggests that this species is a segmental allotetraploid.

We are grateful to Professor M. S. Chennaveeraiah for guidance and to C.S.I.R., New Delhi, for the award of Junior Research Fellowship to one of us (S. B. D.).

### INDUCED FLORAL MUTATION IN *PHYSALIS IXOCARPA* BROT.

NUMEROUS studies in recent years have shown that induced mutations can offer a large number of morphological variations in different parts of the plant<sup>1-4</sup>. So far there is no report on the mutagenesis in *Physalis*. Modifications in the flower and fruit of *P. ixocarpa* mutant and genetical studies of the same have been reported here.

Seeds collected from a single plant formed the stock of present study, were treated with chemical [dimethyl sulphate (DMS), diethyl sulphate (DES) and methyl ethane sulphonate (MES)] and physical (gamma rays) mutagens. The various mutagens were used to study their comparative efficiency in *Physalis*. Dry seeds pre-soaked in water for 12 hours were used for chemical treatments (0.25, 0.50, 0.75 and 1.0% by volume). They were irradiated as such with 20-40 kR of gamma rays. The pre-soaked seeds were treated with freshly prepared aqueous solution of chemicals for 12 hours. The treatment was carried out in test tubes which were intermittently shaken. The seeds treated with chemicals were washed thoroughly with tap water and sown in the nursery. The resulting seedlings were then transplanted in the field to obtain  $M_1$  population. In all four mutant plants were isolated from 0.50 and 1.0% DES, 0.75% DMS and 20 kR treatments respectively, but no mutant plant could be isolated from MES treatments.

The conspicuous floral changes in the mutant were bud open from very young stage (Fig. 1 E), style projecting in bud (Fig. 1 F) and corolla showed slow rate of growth with a very short tube. Stamens which in normal flowers occur in the centre and surrounded the ovary closely (Fig. 1 C; Fig. 2 A) were placed wide apart with exposed ovary projecting above all the floral parts (Fig. 1 G; Fig. 2 D, E). After pollination the fruit developed rapidly and

since the ovary was protruding, the enlarged calyx failed to enclose it. The latter occurred as a cap-like structure at the base of fruit giving curious

FIG. 1

FIG. 2

FIGS. 1-2. Fig. 1 A-H. (Diagrammatic), Comparison of floral characters of control and mutant of *P. ixocarpa*. A-D, Control, note the closed bud in A and aggregated stamens in C. E-H, Mutant showing open bud (E, F) and separated stamens in G. Fig. 2 A-G (Photographs). Flower and fruit characters of control and mutant of *P. ixocarpa*. A-C, Control note aggregated stamens in A and fruit enclosed in enlarged calyx (B, C). D-G, Mutant showing separated stamens in D, E and cap-like structure at the base of fruit (F, G).

look to the mutant (Fig. 1 H; Fig. 2 F, G) as compared to the control in which the fruit was completely enclosed by the enlarged calyx (Fig. 1 D; Fig. 2 B, C).

The mutant on isolation showed poor fruit setting, with thin membranous seeds. All efforts to induce seeds to germinate in petri dishes, pots, paper towels and germination chamber failed. A study of style and stigma after 48 hours of pollination showed that pollen grains germinated and the pollen tube travelled down the style. The mutant also showed 98% pollen fertility.

The seeds obtained from the cross of mutant and control plant germinated readily and progeny segregated in almost 1:1 ratio for open bud *versus* normal (closed) bud (Fig. 1 A, B) character. The open bud individuals in  $F_1$  behaved like the parent and in each back cross again gave 1:1 ratio.

These observations on the mutant behaviour in self and cross-pollination revealed that the original mutant was heterozygous for open bud factor which showed marked pleiotropic effects on other floral and fruit characters. The mutation was a dominant one and since homozygous for gene could not be recovered, the gene in homozygous form might be lethal to the mutant.

As the mutant plant in heterozygous form is viable, the drastic effects in floral characters make it a very useful type for breeding project. The open bud condition, projecting style, widely placed stamens and raised ovary provide the mechanism to ensure cross-pollination in the mutant. The open bud condition gives it the major advantage to carry out emasculation with ease and least injury.

#### ANTIPODAL CELLS IN SOME MEMBERS OF GRAMINEAE

REPORTS on the ephemeral, as well as persistent, large sized, supernumerary and multinucleate antipodals are available<sup>1</sup>. Gramineae are no exception and secondary multiplication of antipodals is the characteristic of this family<sup>3</sup>. *Eleusine indica*, *E. coracana* and *Bromus inermis* show a considerable increase in size of the antipodal cells<sup>2,5,7</sup>. As many as three hundred antipodal cells have been recorded in *Sasa paniculata*<sup>3</sup>, while in *Setaria*

*italica*<sup>6</sup> they are multinucleate. This paper deals with the study of the antipodal cells in *Eleusine africana* Kennedy-O Byrne, *E. compressa* (Forssk.) Aschers. et Schweing and *Chloris gayana* Kunth, members of the Gramineae.

In *Eleusine africana*, *E. compressa* and *Chloris gayana* the development of the embryo sac is of the Polygonum type, and it is conical in shape. In *E. africana* (Fig. 1) there is a deep narrow chalazal pouch. The egg apparatus is typical with two pyriform laterally beaked and apically hooked synergids. The filiform apparatus is present. In *E. africana* the two polar nuclei are separated by a central vacuole while in *E. compressa* and *C. gayana* they are in the centre. In all the three species the antipodal cells before the fusion of polar nuclei are three and they are large and uninucleate (Figs. 1, 3, 5). In *C. gayana* (Fig. 5) they are very large and occupy more than half the space of the embryo sac. Further, in *C. gayana* they are prominently beaked, the beaks being pointed towards the chalazal end. Except in one of the cells of the antipodals in *E. africana* in the rest the vacuoles are not present. On the other hand, they are filled completely with cytoplasm and stain deeply.

FIGS. 1-6. Figs. 1-2. Embryo sac in *Eleusine africana*; (ant; antipodal cell; e, egg; en, endosperm nuclei; pn, polar nuclei; sn, secondary nuclei; syn, synergids; z, zygote; hyp, hypostase). Note three uninucleate antipodals in Fig. 1 and four multinucleate antipodal cells in Fig. 2.  $\times 200$ . Figs. 3-4. *E. compressa*; same as in Figs. 1 and 2 respectively but in Fig. 4 antipodal cells are many.  $\times 125$ . Figs. 5-6. *Chloris gayana*; Embryo sac before fertilisation (Fig. 5) and after fertilisation (Fig. 6); note many antipodal cells and two endosperm nuclei,  $\times 200$ .

After the fusion of the polar nuclei, the embryo sacs of *E. africana*, *E. compressa* and *C. gayana* enlarge and almost become spherical (Figs. 2, 4, 6). In *E. africana* (Fig. 2) and *E. compressa* (Fig. 4) the antipodal cells are four and eight respectively due to the division of one or more cells. However, they are three or four nucleate in *E. africana* and one or two nucleate in *E. compressa*. In both the species they occupy the lateral position of the embryo sac and are baloon-shaped. In *C. gayana* (Fig. 6) the large antipodal cells have divided to form five to eight narrow baloon-like cells which are uninucleate and placed at the chalazal end. Fusion of the nuclei was not observed in any of these antipodal cells. In *E. africana*, a hypostase is formed at the chalazal end just below the antipodal cells (Fig. 2).

In *E. coracana*, *E. indica* and *Dactyloctenium aegypticum* the antipodal cells are quite large and uninucleate<sup>5, 7</sup>. In *E. coracana* and *E. indica* the antipodal cells neither divide nor become coenocytic. Rarely in *E. coracana* division may take place. But in *D. aegypticum* the antipodal cells divide further to form six to ten cells and become coenocytic. In *Pennisetum typhoideum* three to eight nuclei have been recorded in each antipodal cell which finally fuse<sup>1</sup>.

Various functions have been attributed to antipodal cells<sup>5</sup>. Looking into their size, indefinite number, multinucleate condition and high staining capacity they may take part in the nutrition of the embryo sac. Further investigations on the above species and also on *Eragrostis superba*, *Cynodon dactylon* and *Paspalum commersoni* are in progress.

The award of Junior Research Fellowship by the University Grants Commission, New Delhi, to one of us (M. S. M.) is gratefully acknowledged.

ON *GASTROCLONIUM IYENGARII* SRINIVASAN

*Gastroclonium iyengarii* Srinivasan<sup>1</sup> was based on tetrasporic specimens collected first by Srinivasan himself and later by Desikachary from Okla. In some collections made at Porbandar and Veraval, the writer came across a few cystocarpic specimens of this species and a critical study of these was made. Some of the observations are very briefly presented here.

The cystocarpic plants were rather small, though conforming to the typical morphology of this species as described by Srinivasan (Fig. 1). However, one notable difference from the type seen in the present material was the presence of well-developed secondary ramuli. This is particularly well seen in Fig. 1 (lower left, and to a slightly lesser extent, lower right). Srinivasan<sup>1</sup> has stated that the "secondary ramuli are generally absent, but occasionally present, and, when present, rudimentary".

FIGS. 1-2. Fig. 1. Tetrasporic plant showing general habit and well-developed secondary ramuli (arrow),  $\times 1.50$ . Fig. 2. Portion of cystocarpic plant enlarged to show clearly ostiolate cystocarps (arrows),  $\times 4.50$ .

The cystocarps are  $800-1000\mu$  in diameter and approximately of the same height, urceolate, and

with well-defined ostioles (Fig. 2, arrows). It was a surprise to note that the cystocarps were ostiolate. For, in all previous accounts the cystocarp of *Gastroclonium* is described as 'non-ostiolate'. In fact, of the 4 genera included by Kylin<sup>2</sup> in his "*Champia* Gruppe" (= Subfamily Champieae) only *Champia* is considered to have ostiolate cystocarps and this feature has been used by Kylin (*l.c.*, p. 345) to key out *Champia* from the three other genera, viz., *Chylocladia*, *Coeloseira* and *Gastroclonium*. The presence of ostiolate cystocarps in *G. iyengarii* would seem to invalidate this distinction.

Thanks are due to Shri N. R. Mankad for material collected at Porbandar.

## MEIOTIC STUDIES IN SPECIES AND HYBRIDS IN MEDICINAL YAMS

SPECIES of the genus *Dioscorea* L. are cultivated for their edible tubers popularly known as the yams and for the extraction of diosgenin, a source material for the synthesis of steroid hormones. In a breeding programme aimed at the improvement of the medicinal yams, three Mexican species of *Dioscorea*, viz., *D. floribunda* Mart and Gal., *D. composita* Hemsl. and *D. friedrichsthallii* Kunth have been crossed and hybrids obtained<sup>1</sup>. The present note gives an account of the cytology of the species and hybrids.

Meiosis was studied in iron acetocarmine smears of the PMC's. The chromosomes were very small ranging from  $0.3\mu$  to  $1.5\mu$  at MI. Meiosis was regular (Figs. 1 and 2) in the three species with the regular formation of 18 bivalents. The half chiasma frequencies per chromosome were 1.64, 1.61 and 1.52 in *D. floribunda*, *D. composita* and *D. friedrichsthallii* respectively (Table 1). With the present technique employed, it was not possible to find out the presence or otherwise of any sex chromosomes. Since the basic chromosome number of the new *Dioscorea* species is 92, and since meiosis is regular in the 3 species, they may probably represent allotetraploids ( $2n=36$ ) containing 2 genomes, the homologies of which are not known.

The hybrids had fairly regular meiosis except for the presence of a few univalents and higher associations involving 3 and 4 chromosomes (Table I). It could not be made out whether these chromosome associations represent multivalents or

TABLE I  
Frequency of chromosome associations in species and hybrids of *Dioscorea*

those formed due to reciprocal translocations (Fig. 3). Meiotic behaviour of the species alone, however, does not rule out completely the former possibility since such a diploid behaviour of the species could result from a genetic control of chromosome pairing or a gradual diploidisation of homo- or homeologous genomes. When such genomes are brought together in a new combination, it is quite possible for the original homologies to get expressed due to an altered genetic background. The male and female fertilities of the hybrids lend less support to the existence of reciprocal structural changes.

# OCCURRENCE OF GALLMIDGE, *ASPHONDYLIA* SP. (CECIDOMYIIDAE: DIPTERA) AS A PEST OF BRINJAL (*SOLANUM MELONGENA* LINN.) IN INDIA

BRINJAL (egg plant) fruits were found infested with the gall midge, *Asphondylia* sp. at the experimental farm of the Indian Institute of Horticultural Research, Hessaraghatta, Bangalore, for the first time in spring 1973. Maggots feed from inside on the ovary of the flower buds and flowers and on the tissues of the developing fruits. When young flowers are attacked the stamens and pistil degenerate and fruits fail to form. Damage by maggot during development of the fruit is confined to the part of the fruit that is being attacked but nevertheless leads to the distortion of the fruit (Fig. 1). Damage site of the fruit is distinguished by a characteristic colour pattern, viz., greenish spot in case of purple varieties and a dull green colour tending towards white in varieties

with green fruits. Pupa makes an exit hole and slides into it through which the adult fly emerges. Following the emergence of the fly, the fruit cracks along the inner side of the curve (Fig. 1) exposing the fruit tissues and is rendered unfit for marketing. About 2 and 4% of the fruits were damaged by the midge in the spring seasons of 1973 and 1974 respectively, while the attack was not seen during the later part of 1973. Yield loss due to the pest was of the order of 5% in spring 1974. Earlier, Harris<sup>1</sup> (1938) listed *Asphondylia* sp. as one of the injurious pests of brinjal crop in Tanganyika but did not mention the nature of its damage. The present report forms the first record of the pest on brinjal crop from India.

FIG. 1. Damage caused of *Asphondylia* sp.

In spring 1974, observations on the midge incidence were recorded from a chemical control trial conducted for the control of *Leucinodes orbonalis* Guen., wherein the insecticides were sprayed at fortnightly intervals commencing from the first fruit set. The field trial was laid out in randomized block design with three replications on the variety, Dhingra's Multiple Purple.

TABLE I  
Evaluation of insecticides for the control of  
*Asphondylia* sp. on brinjal

| Insecticide     | Dosage<br>Kg<br>ai/ha | Per cent<br>fruit<br>infestation |
|-----------------|-----------------------|----------------------------------|
| Carbaryl        | 1.00                  | 4.12                             |
| Carbaryl        | 2.00                  | 4.08                             |
| Quinalphos      | 0.50                  | 2.78                             |
| Chlorfenvinphos | 0.50                  | 3.21                             |
| Methomyl        | 0.50                  | 3.48                             |
| Pyrethrins      | 0.086                 | 3.49                             |
| Endosulfan      | 0.70                  | 3.13                             |
| Phoixm          | 0.50                  | 3.72                             |
| Control         | ..                    | 3.55                             |
| C.D. (0.05)*    |                       | Not significant                  |

\*Data were statistically analysed after transforming the percentages to arc sin values.

None of the tested insecticides reduced the gall midge incidence significantly, indicating their ineffectiveness in controlling the pest.

Thanks are due to Dr. G. S. Randhawa, Director, for facilities and encouragement and to Dr. Richard, H. Foote, Chief of Systematic Entomology Laboratory, U.S.D.A. (A.R.S.), Beltsville, Maryland, for identification of the pest.

### 'LITTLE LEAF' DISEASE OF GRAPEVINE FROM INDIA

GRAPE (*Vitis vinifera*) is an important commercial crop, extensively cultivated in some parts of India. A number of diseases of fungal origin have been reported from this country but there is no report of any disease caused by virus/mycoplasma-like organisms. However, a number of viral diseases of grapevines have been reported from other grape growing countries<sup>1-4</sup>. Surveys conducted during the year 1973, revealed a disease of grapevine variety 'Merlot Noir' showing 'little leaf' symptoms in the grapevine germplasm collection maintained at the Indian Institute of Horticultural Research, Hessarghatta. The characteristic feature of the disease is smalling of the leaves. The shape and size of the leaves are altered and the leaves become so small and deformed that it becomes difficult to recognize them as grape leaves. The colour of the leaves turn light yellow instead of green and cupping of the leaves was also observed to a certain extent. Internodes are usually close because of the retarded growth of the stem. In early stages, the growth is spindly and tend to become more zigzag at the nodes. The distance between internodes becomes very short and the nodes and internodes are characteristically thin and weak. The general growth of the plant is retarded (Fig. 1). Comparatively very few lateral branches have been observed on the diseased plants. The axillary branches proliferate and produce many secondary branches which are small, thin and weak. No flower and fruit formation has been observed among the infected plants even at the age of 3 years. Roots of the diseased plants have been found to be severely stunted, and produced very few and weak rootlets.

The disease was not transmitted by mechanical sap inoculation to herbaceous hosts though different methods of sap inoculation using different buffers

of different molarities and pH, with or without additives were tried. The disease could be transmitted by grafting or budding of the diseased scion onto the healthy rootstock of the var. Emperor. The symptoms of the disease were observed within 40–50 days following grafting and budding.

FIG. 1. Grape plant showing little leaf symptoms.

**Heat therapy.**—Diseased cuttings were given hot water treatment at 40, 45, 50 and 55° C. for one hour in a water bath and then planted in pots. The cuttings treated at 45 and 50° C. showed recovery 30–35 days after planting and produced normal leaves but the symptoms reappeared after the lapse of 50–60 days.

**Antibiotic therapy.**—Cuttings (rooted and plain) obtained from diseased plants were treated with 1000 ppm solution of Oxytetracycline hydrochloride for 24 hours and then they were planted in pots for further observation. The treated plants showed recovery symptoms within 25–30 days following antibiotic treatment and produced normal size of leaves and shoots (Fig. 2). The effect of oxytetracycline hydrochloride persisted for about 30–35 days after which the symptoms reappeared which could be suppressed further with another dose of 1000 ppm solution of oxytetracycline hydrochloride.

The causal agent of yellows diseases of plants were thought to be due to viruses. At present, considerable evidence suggests non-viral etiology. Japanese workers<sup>5,6</sup> demonstrated the presence of pleomorphic mycoplasma-like bodies in the case of four different yellows diseases and also reported that tetracycline antibiotics produced remission of the disease in plants infected with mulberry dwarf. On the basis of these findings they proposed that yellows disease agents might be mycoplasma-like organisms rather than viruses. Stoddard<sup>7</sup> and Kenknight<sup>8</sup> suggested a sensitivity of certain yellows diseases to antibiotics and later it was confirmed by

Ishii *et al.*<sup>9</sup>. Now many reports have appeared about the mycoplasma-like bodies in the yellows disease and antibiotic therapy of mycoplasma-like organisms have also been demonstrated<sup>9–13</sup>. Recently Goheen *et al.*<sup>14</sup> reported the association of a Rickettsia-like organisms with Pierce's disease of grapevine and its remission with heat treatment.

FIG. 2

FIG. 2. Plant showing recovery after treating with oxytetracycline hydrochloride antibiotic.

The results obtained from the present studies showed that there is a spontaneous remission of little leaf symptoms when the infected cuttings are subjected to heat as well as to antibiotic treatment, indicating thereby that the grapevine little leaf disease may be due to mycoplasma-like organisms. However, this will be confirmed by further studies.

The authors are highly grateful to Dr. G. S. Randhawa, Director, Indian Institute of Horticultural Research, Bangalore, for providing facilities and encouragement. Thanks are also due to Dr. S. S. Negi, for supplying cuttings of diseased grape plant and also the healthy indicator plants of grapes.

### EFFECT OF *HOPLOLAIMUS INDICUS* ON GERMINATION OF GREEN GRAM

DURING our investigation on *Hoplolaimus indicus* very poor germination of green gram (*Phaseolus aureus* Roxb.) seed was recorded, in the culture pots having high nematode population. In order to find out the effect of different population levels of this nematode on the germination of green gram this experiment was laid.

Six different populations in log series, of *H. indicus* viz., 0, 10, 100, 1,000, 10,000, 1,00,000 mixed separately in 100 g steamsterilized moistened sandy soil, each contained in 10.0 cm Petri dishes. One hundred surface sterilized (with 0.2% mercuric chloride solution) green gram seeds, variety Pusa Baisakhi, were sown in each dish in five replications. Dishes were kept at random at room temperature (30–35°C) for six days when final germination was counted. All the seeds were taken out of the soil washed cleanly in running tap water and stained in cotton blue-lactophenol solution. Stained seeds were individually teased and examined microscopically in order to see the parasitic behaviour of the nematodes. Data in relation to seed germination is presented in Table I.

No difference in germination at 0 and 10 inoculum level was noticed while with other treatments it differed significantly. Seedlings of 0 and 10 inoculum levels germinated on the 3rd day whereas in 100 and 1,000 levels the germination was delayed by one day. At 10,000 and 1,00,000 levels very poor emergence of seedlings above the soil

was noticed. However, it was observed that a bunch of secondary roots started coming out just above the infected portion of the developing radicle which turned brownish. Occasionally swelling of roots near infected portion was also noticed (Fig. 1).

FIG. 1. Effect of different population levels of *H. indicus* on germination of green gram seeds.

TABLE I  
Effect of different population levels of *H. indicus* on germination of green gram

| Sl. No. | Population | Germination percentage<br>Mean of 5 |
|---------|------------|-------------------------------------|
| 1       | 0          | 89.0                                |
| 2       | 10         | 88.2                                |
| 3       | 100        | 63.0                                |
| 4       | 1,000      | 38.6                                |
| 5       | 1,0000     | 11.6                                |
| 6       | 1,00,000   | 2.0                                 |
|         | S.E.       | 1.64                                |
|         | C.D. at 5% | 4.84                                |

Presence of nematode was also observed in between seed coat and cotyledon as well as inside the cotyledon at high inoculum levels. A maximum of 10 nematodes (adult and larvae) were found penetrated in the radicle portion of the just sprouted seeds at 10,000 and 1,00,000 inoculum levels. A few were also noticed in the plumule portion. Although, apparently some injury to the leaf primordia was also observed, but no nematode could be traced in this portion. It appears that nematode attack immediately after sprouting of seeds, retarded their growth prevented their emergence out of the soil and eventually caused death.

It is apparent from the above observations that the nematode population plays a vital role in seed germination if present in soil in high population.

Authors are highly grateful to Dr. S. W. Akhtar, Director, Sugarcane Research Institute, Pusa, Dr. A. P. Mishra, Regional Director, Agricultural

Research Institute, Dholi and Shri Harihar Prasad, Asstt. Plant Pathologist, Agricultural Research Institute, Dholi, for their valuable suggestion and help rendered during the investigations.

**RECORD OF A SLUG, *MARIAELLA*  
*DUSSUMIERI* GRAY (ARIOPHANTIDAE :  
BASOMMATOPHORA), AS A NEW PEST  
OF CABBAGE FROM INDIA**

*Mariaella dussumieri* Gray was found damaging the potted cabbage plants during May, 1974 at the Experimental Station of the Indian Institute of Horticultural Research, Hesaraghatta, Bangalore. The slugs inflicted the damage by scraping the epidermis of the leaves and biting holes (Fig. 1).

FIG. 1. Feeding injury by slug.

Mostly the middle whorls of the cabbage head harboured the pest. Slugs were noticed on all the one hundred and fifty plants with an average number of 4 per plant. Apart from direct feeding damage, the pest lowers the market value of the heads by the presence of their excreta. Earlier, Perobrazhenskii (1963) found a grey slug, *Agriolimax agrestis* damaging cabbage at Buryatia Agri. Institute, U.S.S.R. This is the first record of a slug pest on cabbage in India.

Thanks are due to Dr. G. S. Randhawa, Director, Indian Institute of Horticultural Research, Bangalore, for the facilities and to the Director, Zoological Survey of India, Calcutta, for the identification of the pest.

Indian Institute of Horticultural Research,

**A NOTE ON THE ANDALUSITE DEPOSIT OF  
BAGHISHOTI AREA, DISTRICT MIRZAPUR,  
UTTAR PRADESH**

THE area under study forms the easternmost part of the Bijawar formations of the Pre-Cambrian age lying to the south of the great Vindhyan sedimentary basin of the Son Valley, Uttar Pradesh. It lies on the boundary of Bihar and Uttar Pradesh between the Lats.  $24^{\circ} 20'$  and  $24^{\circ} 25'$  and Longs.  $83^{\circ} 25'$  and  $83^{\circ} 30'$ , and falls under the Survey of India toposheet No. 63 P/7.

Andalusite occurs in the area as porphyroblasts and small crystals (see Fig. 1) in the phyllites and schists. The content of andalusite mineral in the phyllite and schists varies from 5 to 20% and appears to be concentrated on the southern and western margin of the Baghishoti granitic pluton. Crystals are well developed and are grey in colour, prismatic in form with square cross-section, average length is being 1 to 1.5 cm, but crystals as long as 10 to 15 cm are also not uncommon. Average specific gravity of andalusite (of five samples) is 3.05.

FIG. 1. Showing porphyroblasts of andalusite in the phyllites.

Andalusite bearing rocks occupy a considerable area in the Baghishoti area. During the present investigation only a part of the area has been examined. However, it has been noted that the percentage of the andalusite mineral in the rock appears to be appreciable. From the preliminary examination it appears that a good reserve of andalusite deposit exists. It is, therefore, suggested

that a more detailed investigation be carried out to ascertain the actual reserves of the deposit. The anticipated reserves are of the order of 8 to 10 m tons. In view of the already known andalusite deposit of Dudhi area and the present occurrence of the andalusite deposit of Baghishoti area, leads the author to suggest the possibility of utilisation in a refractory plant at a suitable site in Mirzapur District.

The author is grateful to Dr. R. C. Misra, Professor and Head of the Department of Geology, Lucknow University, for his help and guidance. He is also thankful to the University Grants Commission for the financial assistance in the form of a Senior Research Fellowship.

### EFFECT OF DINITROPHENOL ON GROWTH AND NITROGEN FIXATION IN CLONES OF *CYLINDROSPERMUM MAJUS*

THE role of respiratory ATP in the process of nitrogen fixation in light is not clearly understood. The effects of respiratory inhibitors on nitrogen fixation in blue-green algae have been reported<sup>1-2</sup>. Such studies have been limited due to the lack of specific inhibitors to separate oxidative and photo-synthetic phosphorylations as the thylakoids are thought to be the sites of both photosynthetic and respiratory activities<sup>3</sup>. The aim of the present study is to observe the effect of 2,4-dinitrophenol (DNP) on the growth and nitrogen fixation in various clones of the heterocystous blue-green alga *Cylindrospermum majus*.

The details of the experimental organism and methods are the same as have been described earlier<sup>1</sup>. The clones were treated in 0.01% DNP for 30 min and grown in 15 ml of basal medium. The growth and amounts of nitrogen fixed by the clones were determined after 15 days (Table I). The DNP was found to inhibit both growth and nitrogen fixation to a limited extent. But clones 1 and 3 grew more and clone 3 fixed more nitrogen as compared with the controls, following treatment with DNP. The formation of heterocysts, commonly regarded as sites of nitrogen fixation, was not suppressed by this treatment. Bahal<sup>4</sup> found DNP-stimulated development of heterocysts in

*Anabaena ambigua* while Tyagi<sup>5</sup> observed the inhibition of heterocyst formation by DNP at a concentration of  $5 \times 10^{-4}$  M in *Anabaena doliolum* and suggested that it was probably due to a block in the supply of respiratory ATP.

TABLE I

Optical density and cell nitrogen of various clones of *Cylindrospermum majus* (Average values of two replicates)

| Clone No. | Control       |             | DNP treatment |             |
|-----------|---------------|-------------|---------------|-------------|
|           | Growth (O.D.) | Cell N (mg) | Growth (O.D.) | Cell N (mg) |
| 1         | 0.067         | 0.364       | 0.092         | 0.336       |
| 2         | 0.097         | 0.392       | 0.090         | 0.392       |
| 3         | 0.090         | 0.301       | 0.102         | 0.462       |
| 4         | 0.127         | 0.497       | 0.092         | 0.476       |
| 5         | 0.122         | 0.567       | 0.100         | 0.434       |
| 6         | 0.122         | 0.406       | 0.057         | 0.322       |

The statistical analysis of variance revealed that neither the control nor the DNP-treated clones showed any significant variation in nitrogen fixation. These results indicate that in the process of nitrogen fixation in light, ATP produced from the oxidative phosphorylation is not needed. The requirements of energy and carbon skeletons are fulfilled mainly through the process of photosynthesis. The oxidative phosphorylation may supply ATP only when nitrogen fixation occurs under dark conditions. Besides, ATP produced on breakdown of polyphosphates<sup>6</sup>, which are abundant in blue-green algae<sup>7-10</sup>, may also be a source of energy in these organisms.

The author is thankful to Professors H. D. Kumar and Y. D. Tiagi for guidance.

## SHORT SCIENTIFIC NOTES

### Vitamin C Content in *Moringa* Pod Vegetable

The tender pod-like fruits of *Moringa* tree are used in the preparation of various types of vegetable-curries and pickles throughout India. The pods start ripening during the last week of March and are then cooked alongwith "Sambar".

In our studies on the genetical improvement of *Moringa* for wood-pulp we came across extensive variation in the taste of pods of *M. oleifera* and *M. concanensis* which varied from very sweet to extremely bitter. Different grades of sweetness of both raw and cooked pods of *M. oleifera* was the basis for selection of clones 3, 6, 7 and 10 from vegetatively propagated trees planted under standard nursery environment. From amongst the four clones of *M. oleifera*, clones 6 and 7 flower almost throughout the year and they, therefore, fall in the category of "Baramasi" varieties. Both leaves and fruit-juice of *M. oleifera* are known to be rich in vitamin C content<sup>1-4</sup>.

The fresh pods of the four sweet clones of *M. oleifera* and of one bitter clone of *M. concanensis* were screened for ascorbic acid content. The fruits from each tree were also collected randomly during II week of April and a composite sample of 10 g was ground with 12% oxalin acid. Ascorbic acid content was then determined by titremetric method using 2-6 dichlorophenol indophenol. The results are given in Table I. *M. concanensis* had the highest ascorbic acid content in the bitter fruit of the clone evaluated.

TABLE I

+ Present; — Absent;

Amongst the sweet clones of *M. oleifera* clones 7 and 3 had the highest amount of ascorbic acid followed by 10 and 6. Clone 6 although sweet has a poor yield in spite of its long flowering period due to sterility. Work is also in progress in this

Laboratory on screening of new germplasm of *M. oleifera* for other important nutritive contents such as proteins, carbohydrates and other vitamins.

We are grateful to professor T. S. Sadasivan, for suggesting the problem of screening the sweet clones of *M. oleifera* for vitamin C content.

### Comparative Observations on Glume, Spikelet and Stomatal Length in Haploid, Diploid and Tetraploid Rices

Spontaneous occurrence of tetraploids in the  $F_2$  generation of two diploid rice varieties, viz., J.B.S. 820 and AC. 1225 has been reported<sup>1</sup>. AC. 1225 has long sterile glume while in J.B.S. 820 the sterile glumes are asymmetrical in length. One haploid plant was later isolated from the  $F_2$  population. An attempt was made to study the ploidy effect on the glume (sterile lemma), spikelet and stomatal length of the cytotypes.

The haploid plant, diploid parents (J.B.S. 820 and AC. 1225) and a typical tetraploid Tet-6, were studied. All the cytotypes had asymmetrical glumes and therefore, glumes on lemma and palea sides were separately observed. Stomata of dorsal side of the second leaves from top were always selected. One hundred measurements were taken in all cases.

Data are presented in Table I along with the range and mean.

There is a linear increase in the mean length of spikelet, glume and stomata from haploidy to tetraploidy. The proportion of increase is, however, not the same in all characters. The mean spikelet length of diploids was approximately twice the mean length of haploid while the increase was marginal from diploidy to tetraploidy. A similar trend was noted in the case of glume length on the palea side; there was overlapping of measurements. The ploidy effect was thus most pronounced in the length of lemma side glume.

TABLE I  
Spikelet, glume and stomatal length in cytotypes of rice

| Charac-<br>ters | Spikelet length in mm |                 | Glume length in mm |                 |            |                 | Stomatal length in $\mu$ |                 |
|-----------------|-----------------------|-----------------|--------------------|-----------------|------------|-----------------|--------------------------|-----------------|
|                 |                       |                 | Palea side         |                 | Lemma side |                 |                          |                 |
|                 | Types                 | Range           | Mean               | Range           | Mean       | Range           | Mean                     | Range           |
| Haploid         | 3.50-4.50             | 4.01 $\pm$ 0.07 | 0.50-3.90          | 2.30 $\pm$ 0.17 | 0.50-2.00  | 0.97 $\pm$ 0.12 | 4.50-7.00                | 5.64 $\pm$ 0.07 |
| J.B.S. 820      | 6.98-8.60             | 7.77 $\pm$ 0.05 | 3.00-7.00          | 5.42 $\pm$ 0.14 | 2.10-6.00  | 3.97 $\pm$ 0.14 | 5.50-9.10                | 6.68 $\pm$ 0.09 |
| AC. 1225        | 7.30-9.00             | 8.36 $\pm$ 0.06 | 4.70-8.60          | 6.56 $\pm$ 0.28 | 3.80-9.60  | 5.05 $\pm$ 0.18 | 6.20-8.00                | 6.63 $\pm$ 0.06 |
| Tet-6           | 9.07-10.54            | 9.91 $\pm$ 0.02 | 5.00-13.00         | 7.88 $\pm$ 0.21 | 5.00-10.00 | 6.68 $\pm$ 0.19 | 7.10-10.00               | 8.44 $\pm$ 0.11 |

The linear increase in the mean stomatal length from haploidy to diploidy and from diploidy to tetraploidy was also marginal with overlapping of measurements.

#### An *Alternaria* Leaf Spot of Tapioca

Tapioca plants (*Manihot esculenta* Crantz), aged, about 7 months, in the instructional farm of the College of Agriculture, Vellayani, were affected by a leaf spot disease during April 1974. The spots were observed mainly near the tips of the lobes of the leaf. They were minute, scattered with whitish grey centre and brown margin. Often the leaf tips dried due to the formation of a number of spots. Rarely, spots were also observed on the basal part of the leaf blade. Repeated isolations from the infected regions yielded an *Alternaria* species. The pathogenicity of the same was established by artificially spray inoculating tapioca plants with 6 day old culture of the organism. Typical leaf spot symptoms were formed in 7-10 days after inoculation. The fungus was reisolated into pure culture from inoculated plants.

A detailed study of the morphological characters of the fungus on potato-dextrose agar revealed the following characters. The mycelium was slightly dark and 2.25-10.5  $\mu$  wide. Conidia mostly single, sometimes in chains of 1-3, provided with 1-9 transverse septa and a maximum of 3 longitudinal septa. Conidia were dark brown, obclavate, rarely elliptical, attenuate; beak short, rarely long. Including the beak the conidia measured 14.04-76.38  $\mu$  (40.07  $\mu$ ) the beak alone was 8.13-61.75  $\mu$  in length (15.37  $\mu$ ). The breadth at the basal region ranged between 5.68  $\mu$ -13.0  $\mu$  (10.75  $\mu$ ) and

at the base of the beak it was 3.25  $\mu$ -8.12  $\mu$ . The conidiophore measured on the average 78.5  $\mu$   $\times$  3.25  $\mu$  with 6-9 septations and 1 or 2 lateral scars.

The morphological details closely resembled these of *Alternaria palandui* Ayyangar, reported from *Allium* species by Ayyangar<sup>1</sup> (1928). Artificial cross inoculation of *Allium cepa* L. by the isolate from tapioca gave positive results. From the close resemblance of the morphological characters and by the cross inoculation tests carried out, the isolate from tapioca was identified as *A. palandui* Ayyangar. Tapioca is recorded for the first time as a host of this organism causing leaf blight disease.

#### Occurrence of White Grubs in Haryana

A serious incidence of white grub on *bajra* (*Pennisetum typhoideum*) and groundnut was observed during 1971 in village Mandhana (District Mohindergarh). During October, 1971 one square metre area in a harvested *bajra* field was carefully dug which contained, at depths varying from 30 to 96 cm, 23 adults, 3 pupae and 2 first instar grubs of *Lachnosterna fissa* Brenske.

A severe insect damage to newly sprouted *ber* (*Ziziphus mauritiana* Lmk.), leaves was reported from Kankraula (District Gurgaon) in the first week of July, 1972. 27 adult beetles were collected from upper 15 cm sandy-soil layer of the orchard and these represented 4 species of white grubs, viz., *Holotrichia insularis* Bren. (21 specimens), *Anomala ruficapilla* Burm. (3 specimens),

*A. dorsalis* F. var *fraterna* Burm. (2 specimens), and *A. bengalensis* Bl. (1 specimen).

Peach tree leaves at Gurgaon were severely damaged by some insect during July, 1972. Spraying of a medium sized tree with endrin 0.02% emulsion at sun-set knocked down 60 adults of white grub, *Holotrichia* sp. nr. *problematica* Bren. which were collected next morning.

These reports indicate that several species of Scarabaeid white grubs are becoming serious pests of *kharif* crops as well as fruit trees in Haryana.

Out of the white grub species mentioned in this communication, *H. insularis* and *A. bengalensis*

have earlier been reported to damage sorghum, bajra, sugarcane, chillies, groundnut, suna-hemp, brinjal, cucurbits, ladys' finger and cowpeas in Rajasthan (Srivastava and Khan, 1963)<sup>1</sup>.

Thanks are due to Dr. P. K. Sen-Sarma, Forest Research Institute, Dehra Dun, for identifying the insects.

## REVIEWS AND NOTICES OF BOOKS

---

Annual Review of Fluid Mechanics (Vol. 4). By M. V. Dyke, W. G. Vincenti and J. V. Wehausen. (Annual Reviews Inc., 4139 El Camino Way, Palo Alto, Calif., Calif. 94306), 1972. Pp. ix + 504. Price \$ 12.00 (U.S.A.), \$ 12.50 (Elsewhere).

Within the short period of a few years since the commencement of publication of these annual reviews, they have earned a permanent and respected place in the literature of fluid mechanics. Volume 4 maintains the high standards set by its predecessors, and offers rich and diverse fare which will be both interesting and instructive to fluid dynamicists. Among the subjects covered, about a third is of direct interest to engineers (heat disposal from power generation, chemically reacting flows, vortex breakdown, cavity and wake flows, wing-body interaction in aircraft); another third is geophysical or environmental (mantle convection, rotating and stratified flows, magnetohydrodynamics of the earth's core, self-gravitating gaseous disks, oil spreading on sea). There are several articles of general interest also (self-similar solutions, periodic flows, liquids containing bubbles, sailing, bounds on flow quantities), and one, on the locomotion of protozoa.

Experimental workers will probably feel that there are too few articles for them in this volume as in previous ones, but by and large the Review will be found to be a valuable survey of some of the most interesting recent investigations in fluid mechanics.

It would be very useful to have this series in paperback, so that more workers could possess their own copies, as I am sure many would like to.

R. NARASIMHA.

Quantum Mechanics in a New Key. By Alfred Lande—Exposition Press, 1973 (Exposition Press, Inc., 50 Jericho Turnpike, Jericho, New York 11753), 1973. Pp. x + 131. Price \$ 6.50.

This book is the third in a series which represent the efforts of the author, a renowned physicist, to clarify the foundations of quantum mechanics and demystify the notions of complementarity, duality, etc., which are so prominent in usual treatments. He attempts to provide a well motivated derivation of the usual computational rules which involve superposable vectors in a complex Hilbert space and operators on these representing physical quantities. The starting point of this derivation is a set of non quantum postulates, governing a probabilistic scheme of description of the results of measurements. This is the part of the book I found most interesting chapters II to V—even though the argument does seem after the fact at points. The first chapter is meant to provide a negative motivation for the rest and consists of an attack on the usual presentations. I for one failed to understand the covariance objection to Bragg reflection and the oscillator dilemma, both of which are intended to discredit the usual interpretation. One cannot help feeling that the author deliberately sets up a very naive argument, the better to demolish it later. The treatment of the Einstein Podolsky Rosen paradox—page 111—is unique in that it simply denies the existence of correlations in the results of measurements on two spatially separated parts of a system which had been together in the past. This would have surprised the authors of the paradox as much as those who tried to rebut their viewpoint!

In view of the many inaccuracies and distortions, I do not think the claims of pedagogic value made

for the book are justified. Specialists in the foundations of quantum theory may, however, feel like taking a look. In the case of at least one to whom I showed the book, the look was not a long one!

RAJARAM NITYANANDA.

**Pharmacognosy of Powdered Crude Drugs.** By M. A. Iyengar. Pp. xiii + 63. Price Rs. 15; **A Hand Book of Pharmacology.** By M. A. Iyengar. Pp. 98. Price Rs. 15.00. (Published by the Author. College of Pharmacy, Kasturba Medical College, Manipal-576119), 1974.

The technical education has made tremendous progress in recent years. One of the major drawbacks to cope up with the progress is non availability of the text books. The text books on a subject like Pharmacognosy are very few and most of them are written by foreign authors. Dr. M. A. Iyengar has succeeded in publishing two books in Pharmacognosy, namely *A Hand Book of Pharmacognosy* and *Pharmacognosy of the Powdered Crude Drugs*.

*A Hand Book of Pharmacognosy* mainly deals with the basic knowledge pertaining to the official source, family, major chemical constituents and their tests, the Pharmacological and therapeutical uses of about eighty crude drugs. The author has taken pains to describe the microscopic characteristics of some of the powdered crude drugs commonly used, in his book *Pharmacognosy of Powdered Crude Drugs*. The author has maintained the originality in describing the diagrammatic features of these drugs.

These two books are very useful for the para medical students particularly to those who undergo Pharmacy course. The *Hand Book of Pharmacognosy* is particularly useful to the students undergoing the course in Diploma in Pharmacy.

V. B. DESAI.

## ANNOUNCEMENTS

### Award of Research Degrees

Utkal University, Bhubaneswar, has awarded the Ph.D. degree in Mathematics to Shri Brajakishore for his thesis entitled "Summability of Fourier Series and Allied Problems"; Ph.D. degree in Chemistry to Shri Santosh Kumar Mahapatra for his thesis entitled "Studies of Heterocyclic Compounds". Ph.D. degree in Science (Zoology) to Shri Murari Mohan Dash for his thesis entitled "Studies on the the Population and Biometry of the Potato Aphid,

*Myzus* (Necterosiphon) *persicae* Sulzer (Aphididae-Homoptera, Insecta)".

The M.S. University of Baroda has awarded the Ph.D. degree in Botany to Shri Dharmendrakumar Natwarlal Thaker for his thesis entitled "Floristic and Ethnobotanical Studies on Kawant range forests in Central Gujarat"; Ph.D. degree in Psychology to Shrimati Siddhida Jahardan Mehta for her thesis entitled "An investigation into the Effectiveness of Programmed Material in English for developing Reading Ability".

Karnatak University, Dharwar, has awarded the Ph.D. degree in Chemistry to Shri Goudar Timmanagoud Ramanagoud for his thesis entitled "Physico-Chemical Investigations on Complexes of Some Transition Metals".

Sri Venkateswara University, Tirupati, has awarded the Ph.D. degree in Chemistry to Shri Syed Ghouse Peeran for his thesis entitled "Synthesis and spectral studies of Cis (Z) and Trans (E) Unsaturated Sulphide—Sulphones and Disulphides"; Ph.D. degree in Physics to Shri B. P. Nagireddy, Shri S. Mohan and Shri J. Lakshman Rao for their theses entitled "Studies in Low Temperatures—Elastic and Thermal Properties of Some Ferrites", "Studies in Solid State Physics Effect of Temperature of Electrical Conductivity and Hall Effect in Thin Films of Silver and Copper" and "Studies on the Optical Absorption spectra of some first group transition metal ions in certain Inorganic and Organic Crystals" respectively.

# CURRENT SCIENCE

*Fortnightly Journal of Research*

Issued on the 5th and 20th of each month

## IMPORTANT NOTICE TO SUBSCRIBERS OF THE JOURNAL

As you are aware CURRENT SCIENCE has been coming out regularly on the due dates as above with the kind co-operation of you all.

On account of the sharp increase in the cost of quality paper used for the Journal, increase in rates of block making materials, increase in postal rates and the increase in the establishment charges it has become impossible for the Association to issue the Journal, unless the subscription rates are put up.

The Working Committee of the Association has reluctantly decided at its last meeting, to enhance the subscription of CURRENT SCIENCE with effect from 1st January 1975 for institutions :

India Rs. 84/- Foreign Rs. 150.00 \$ 20.00 or £ 8.0.0

The subscription rates for individual subscribers however will remain the same as now.

The continued co-operation of our subscribers is requested.

## ABSTRACT

The need for modifying the potential function  $V(\psi)$  corresponding to the rotation about the bond  $C^\alpha-C$  in peptides and polypeptides, from three-fold minima and a low barrier, to  $V(\psi) = 2.0 (1 - \cos 2\psi)$  is stressed. Taking the new expression for  $V(\psi)$  it is shown that the theory for a pair of peptides is in good agreement with the conformational data obtained from the crystal structures of peptides and proteins. Applications of the new form of  $V(\psi)$  to LL and LD bends in peptides and proteins also improve the agreement between theory and observation.

## INTRODUCTION

IN connection with the calculations of the energy of a dipeptide unit corresponding to the conformation  $(\phi, \psi)$ , suitable potential functions for various types of interactions have been used by different laboratories. Although differing in minor details, all of them are essentially similar<sup>1-4</sup>. Considering in particular, the potential functions associated with the torsion angles  $\phi$  and  $\psi$ , the functions in common use have the following forms:

$$V(\phi) = \frac{1}{2} V_\phi (1 \pm \cos 3\phi) \quad (1)$$

with  $V_\phi$  varying between 0.6 and 1.5 kcal/mole; and

$$V(\psi) = \frac{1}{2} V_\psi (1 - \cos 3\psi) \quad (2)$$

with  $V(\psi)$  having values between 0.25 and 1.0 kcal/mole.

As a justification for using a low barrier for  $V(\psi)$ , it is stated that the barrier to the internal rotation about the  $C^\alpha-C$  bond in compounds of the type  $CH_3C(X)O$  ( $X = H, F, Cl, Br, N, OH$ ) is found to be very small and having three-fold minima<sup>5</sup>. However, for the rotation  $\psi$  about the bond  $C^\alpha-C$  in the peptide group, in which the nitrogen atom is attached to the C-atom on one side and to the  $C^\alpha$ -atom on the other side, as shown in Fig. 1, the nature and height of the barrier could be different. A recent analysis of the distribution of observed conformations in small peptides and in the non-helical regions of proteins indicated that the barrier to rotation about the bond  $C^\alpha-C$  is not three-fold<sup>6</sup>. These observed conformations are found to cluster within  $\pm 30^\circ$  around

$\psi = 0^\circ$  and  $\psi = 180^\circ$ , corresponding approximately to the *trans* and *cis* positions of the nitrogen atoms, as shown in Fig. 2<sup>6</sup>. Infrared studies of amides made by Shimanouchi<sup>7</sup> also indicated that the stable conformations that occur corresponded to either  $\psi = 0^\circ$ , or  $180^\circ$ . These observations suggest that the potential  $V(\psi)$ , for rotation about the bond  $C^\alpha-C$ , can be of the form,

$$V(\psi) = \frac{1}{2} V_\psi (1 - \cos 2\psi) \quad (3)$$

FIG. 1. Diagrams illustrating the differences in geometry related to the rotation about the bond  $C^\alpha-C$ , in the case of (a) a carboxylic acid and (b) a peptide.

FIG. 2. (a) and (b) show respectively, the *trans* and *cis* positions of the nitrogen atoms in a dipeptide.

In view of this, preliminary quantum chemical calculations, using an *ab-initio* method, were carried out by us sometime ago on a model compound  $NH_2CH_2CONH_2$ . For  $\psi = 90^\circ$ , the total energy

† Contribution No. 55 from the Molecular Biophysics Unit, Indian Institute of Science, Bangalore, India.

was found to be more by as much as 6.0 kcal/mole for  $\psi$  near  $90^\circ$  as compared to the energy at  $\psi = 0^\circ$  or  $180^\circ$ . Another set of calculations using IEHT method developed by Rein *et al.*<sup>8</sup> and using the Cusach approximation, on the same model compound, indicated that the total energy variation with respect to  $\psi$  has minima at  $\psi = 0^\circ$  and  $\psi = 180^\circ$  with a maximum at  $\psi = 90^\circ$ . The total energy difference between maxima and minima was found to be of the order of 4.5 kcal/mole. Recent calculations of Pople and Radom<sup>9</sup>, for the same model compound using an *ab-initio* procedure, have indicated minima at  $\psi = 0^\circ$  and  $\psi = 180^\circ$ , for  $\phi = 90^\circ$  (since the calculations have been done only at intervals of  $60^\circ$ , no precise value for maxima, and the difference between maximum and minimum energy, could be obtained). In performing these calculations, the total energy was first minimized with respect to  $\phi$ , and then with respect to  $\psi$ . Therefore, the total energy variation with respect to  $\psi$  which gives minima at  $\psi = 0^\circ$  and  $\psi = 180^\circ$  is indicative of the fact that the form of the internal rotational potential function  $V(\psi)$  around C—C bond has two-fold minima. These quantum-chemical calculations also suggest that the barrier to the internal rotation about C $^\alpha$ —C bond has a large value compared to the currently accepted value of 1.0 kcal/mole or less. Though the quantum-chemical calculations give the total energy difference, the contributions from other interactions in this range is expected to vary little and therefore, the barrier to internal rotation about the bond C $^\alpha$ —C is taken to be as large as 4.0 kcal/mole.

#### APPLICATION OF THE MODIFIED $\psi$ -POTENTIAL

The potential energy variation, for a pair of linked peptide units having a C $^\beta$ -atom, using the 6-exp non-bonded potential function, the electrostatic interaction energy as given in Ref. 1 and the torsional potential  $V(\psi)$  as

$$V(\psi) = 2.0(1 - \cos 2\psi) \quad (4)$$

is shown in Fig. 3 (b). In view of our recent quantum chemical calculations made on simple amides which indicated that the barrier height to the internal rotation around the N—C $^\alpha$  bond is very small, we have neglected the term  $V(\phi)$ . The hydrogen bond energy contribution is also not included. The convention used for drawing the potential energy maps is as suggested by IUPAC-IUB Commission<sup>11</sup>, and the dihedral angles ( $\phi, \psi$ ) are defined as given in their recommendation. By making the only change

$$V(\psi) = 0.25(1 - \cos 3\psi) \quad (5)$$

the variation in energy is shown in Fig. 3 (a). The main difference between Fig. 3 (a) and Fig. 3 (b) is that the region between  $\psi = 60^\circ$  and  $120^\circ$  is

practically forbidden for all conformations of an alanine dipeptide unit according to the new  $\psi$ -potential, whereas it is not so with the old potential. This is because of the fact that the  $\psi$ -potential rises by 4.0 kcal/mole for  $\psi = 90^\circ$ .

In Fig. 3 (b) are also plotted the ( $\phi, \psi$ ) values for non-glycyl linear oligo-peptides (tri-, tetra- and hexa-peptides) as well as cyclic peptides. These points lie in the low energy regions of the map. The low energy regions shown in Fig. 3 (b) thus become the allowed conformations for a dipeptide. In a polypeptide chain, though some of the low energy regions of a pair of peptide unit may become disallowed, it is obvious that the disallowed conformations for dipeptide unit will not be a low energy conformation for a polypeptide chain. Thus, if a comparison of Fig. 3 (a) or 3 (b) with the empirical plot obtained from the protein data of Pohl<sup>10</sup>, and shown in Fig. 3 (c) (to facilitate ready comparison) is made, much better agreement is obtained for Fig. 3 (b) than for Fig. 3 (a). However, while making the comparison of Fig. 3 (c) with either Fig. 3 (a) or 3 (b), it should be remembered that the  $\alpha$ -helical type of conformations near ( $-60^\circ, \pm 60^\circ$ ) and the  $\beta$ -structure conformations have been included in Pohl's diagram, although they are not particularly favoured for a dipeptide conformation. This explains the essential difference between Fig. 3 (b) and Fig. 3 (c).

Fig. 3 (a). Isoenergy curves for a pair of peptide units linked at C $^\alpha$  ( $V_{tot} = V_{nb} + V_{es} + V(\phi)$ ) at intervals of 1.0 kcal/mole, for an alanyl dipeptide, with  $V(\psi)$  having three-fold minima at  $-180^\circ$ ,  $-60^\circ$  and  $+60^\circ$  and a small barrier of 0.5 kcal/mole.

In all our calculations, we have considered the geometry for the peptide unit having  $\tau(C^\alpha-C-O) = 115.6^\circ$  and  $\tau(N-C_2^\alpha-C) = 112.5^\circ$ .

FIG. 3 (b). A similar diagram for an alanyl dipeptide unit, but with  $V(\psi)$  having two-fold minima at  $\psi = 0^\circ$  and  $180^\circ$  and a barrier of 4.0 kcal/mole in between them at  $\psi = 90^\circ$ . The values of  $(\phi, \psi)$  as obtained from crystal structure data of small peptides for non-glycyl residues are shown by cross (X).

FIG. 3. (c) Isoprobability curves in the  $(\phi, \psi)$ -plane, reported by Pohl<sup>10</sup> (including glycyl examples). The curves at intervals of factors of 2. Note the similarity between Figs. (b) and (c).

The energy for a glycyl dipeptide unit, using the new potential function for  $V(\psi)$  is shown in Fig. 3 (d). In Fig. 3 (d) are also plotted the

$(\phi, \psi)$  values for linear oligopeptides and cyclic peptides for glycyl residues along with the  $(\phi, \psi)$  values for glycyl residues in the non-helical regions of lysozyme, myoglobin and chymotrypsin as obtained from crystal structure data. The distribution of points clearly shows that the energy map drawn by using the new potential function for  $V(\psi)$  is in much better agreement with the observed data than the energy maps reported so far. Similarly, if the isoenergy contours of Fig. 3 (d) are compared with the iso-probability curves given by Pohl<sup>10</sup> for glycyl residues (not shown here), as obtained from protein crystal data, the agreement is found to be excellent.

FIG. 3 (d). Diagram similar to (b), but for a glycyl dipeptide unit, using  $V(\psi)$  having two-fold minima and a barrier of 4.0 kcal/mole. The values of  $(\phi, \psi)$  for glycyl residues only, in peptides and proteins are plotted. X—denotes data from peptides; •—denotes data from lysozyme, chymotrypsin and myoglobin.

#### APPLICATION TO BETA-BENDS

The theory of these bends was published by Chandrasekaran *et al.*<sup>13</sup>. This theory predicted minima for an LL bend for values of  $(\phi_2, \psi_2)$ ,  $(\phi_3, \psi_3)$  close to  $(-50^\circ, -50^\circ)$ ;  $(-110^\circ, 40^\circ)$  and to  $(-60^\circ, 100^\circ)$ ;  $(60^\circ, 40^\circ)$ . Thus,  $|\psi_3|$  was always greater than  $30^\circ$ . However Table II and Table III of Ref. 13 show that, for most of the observed conformation, the value of  $|\psi_3|$  lies between  $0^\circ$  and  $20^\circ$ . The mean of  $|\psi_3|$  for observed data as obtained from these tables of Ref. 13 in lysozyme and chymotrypsin is  $14^\circ$  and for small peptides is  $9^\circ$ , thus leading to a discrepancy between theory and observation. When the calculations were repeated using the new potential

$V(\psi)$ , the minimum energy conformations of the LL bend come close to  $(-60^\circ, -30^\circ)$ ,  $(-90^\circ, 20^\circ)$  and  $(-60^\circ, 140^\circ)$ ;  $(60^\circ, 10^\circ)$ , agreeing well with the observations.

Thus, the data presented in this note indicate that a form of the  $\psi$ -potential with two-fold minima and a relatively high barrier of 4.0 kcal/mole is the one that may have to be adopted for the classical energy calculations.

#### ACKNOWLEDGEMENT

We wish to thank Professor G. N. Ramachandran for his interest in the work. This work was partially supported by U.S. Public Health Services Grants AM-15964 (in Bangalore) and AM-11493 (in Chicago).

### ALL-INDIA SYMPOSIUM ON APPLIED OPTICS AND EXHIBITION OF OPTICAL INSTRUMENTS, BANGALORE

**A**n all-India Symposium on Applied Optics and Exhibition of Optical Instruments were held during 28-30 November, 1974, at the Indian Institute of Science, Bangalore.

The symposium was convened under the joint auspices of the Central Instruments and Services Laboratory, Centre for Information Processing and Department of Physics, Indian Institute of Science. Profs. M. Ramakrishna Rao, S. V. Pappu and P. S. Narayanan were the conveners. About 100 delegates from all over India participated in the symposium.

The proceedings of the three-day symposium began with the inaugural function. Prof. S. Bhagavantam, former Scientific Adviser to Minister for Defence, delivered the inaugural address. Prof. S. Dhawan, the Director of the Institute, apprised the gathering of the various activities of the Institute in the field of Applied Optics. Sri. S. M. Krishna, Minister for Industries, Karnataka State, declared open the exhibition and released the Souvenir.

Prof. H. Narasimhaiah, Vice-Chancellor of Bangalore University, presided over the inaugural function.

About forty papers were presented in five technical sessions under the following headings: Lasers and Applications; Optical Processing and Holography; Optical Thin Films and Materials; Optical Measurements and Testing; Optical Instruments and Devices.

An exhibition of various optical instruments manufactured in India was held along with the symposium. About twenty companies participated in the exhibition, bringing their products to the attention of the scientists and engineers working in the field of Applied Optics.

Prior to the symposium a four-week winter school in optical engineering was organised for college teachers under the education program. About twenty teachers and scientists from colleges and research organisations attended the winter school.

# EVALUATION OF NUMERICAL EVIDENCE IN FORENSIC COMPARISON ANALYSES CRITERIA FOR IDENTITY AND ASSESSMENT OF EVIDENTIAL VALUE

B. N. MATTOO

Forensic Science Laboratory, Byculla, Bombay-8

## ABSTRACT

Two alternative methods of evaluating a discrepancy index are discussed, with a view to match crime/clue material with a comparison/source sample. One is put as  $\theta = \sum_{i=1}^N (Q_i - 1)^2/q_i^2$  (cf. Parker's C) and another,  $\theta = \frac{1}{N} \sum_{i=1}^N Q_i (1 + t_i q_i)$  based on the discrepancy quotient Q and the overall coefficient of variation q. A simple evaluation of the uniqueness of a crime material is described on the basis of attributes measured in the source and the population, their mean values and the respective standard deviations.

**F**ORENSIC comparison analyses are undertaken to determine if a "crime sample" has originated from an alleged source. The inference drawn from non-numerical analyses like tool marks examination, e.g., in forensic ballistics or hand-in-glove fit of a crime sample with its remnant available elsewhere, can (when good characteristic matches are observed) be interpreted directly without "any reasonable doubt". This however is not possible in (numerical) material analyses<sup>1</sup>. In the former the characteristic match is obvious, but in the latter one has to cautiously interpret the results. Forensic analytical data have been evaluated by Parker<sup>2</sup> (human hair), Hoffman<sup>3</sup> (soils) and Lawson and Framan<sup>4</sup> (general).

Evaluation of analytical data in forensic problems is considered here firstly to establish if the crime and comparison (alleged source) samples match and secondly, that if these do so, then what proportion of the population of such material in question attain the levels of the attributes analysed. The lower it is, the more weighty is the evidence.

## 1. CRITERIA FOR IDENTITY

For matching or otherwise of a crime sample with the source, Parker<sup>2</sup> defined the discrepancy index, C, as:

$$C = \sum_{i=1}^N D_i^2 = \sum_{i=1}^N (X_i - Y_i)^2/\lambda_i^2 \quad (1)$$

where  $X_i$  and  $Y_i$  are the values for the  $i$ -th attribute measured in the crime sample and the alleged source respectively.  $\lambda_i$  is the combined standard deviation resulting from the standard deviation  $\delta_1$  in the crime sample, due to the measurement errors and the standard deviation  $\delta_2$  in the source, mainly due to the intrinsic variability;  $\lambda^2 = \delta_1^2 + \delta_2^2$ . If N uncorrelated attributes are measured, C is distributed as  $\chi^2$  with N degrees of freedom, if the crime sample originates from the alleged source. The observed C may be compared with the critical value for C, viz.,  $C_0$ , from the statistical  $\chi^2$  tables. At a given chosen probability value, say 0.01 (Parker),

if  $C < C_0$  then the crime sample could stem from the alleged source, and if in fact it does, the probability of finding  $C > C_0$  is as low as 0.01.

An alternative to Parker's C is described here, based on discrepancy quotient (*vide infra*) which is significant to the forensic analyst. Moreover, Parker used  $\ln c$  as against  $c$  (concentration); this is laborious, without making any significant difference in the results using  $c$  conveniently.

Let the values of a given attribute in the crime sample and the alleged source be:  $X_1 \pm \delta_1$  and  $X_2 \pm \delta_2$  respectively, and let  $\delta_1/X_1 = q_1$  and  $\delta_2/X_2 = q_2$ . We define discrepancy quotient, Q, as  $Q = X_1/X_2$ , we have  $(X_1 \pm \delta_1)/(X_2 \pm \delta_2) = Q \pm k$ , where  $k/Q = \sqrt{q_1^2 + q_2^2} = q$  (let). Parker's element of discrepancy index, viz.,  $D_i^2 = (X_1 - X_2)^2/(\delta_1^2 + \delta_2^2)$  can now be put as:  $D_i^2 = (Q - 1)^2/(Q^2 q_1^2 + q_2^2)$ . Discrepancy quotient, Q, will be useful in our discussion, if we impose the condition that  $Q \geq 1$ , no matter whether the attribute in the crime sample is greater than that in the source or *vice versa*. It will indicate a Q-fold discrepancy in the value of the attribute in the crime sample and source and calculations of the discrepancy index (*vide infra*) will be to the benefit of the accused. We now define  $\Delta_i$ , a normal deviate with unit standard deviation as

$$\Delta_i^2 = (1/Q - 1)^2/(k')^2, \text{ where } k'/(1/Q) = q.$$

∵ if  $(X_2 \pm \delta_2)/(X_1 \pm \delta_1) = (1/Q \pm k')$ , we have,  $k'/(1/Q) = q$ . For identity of crime sample and source, we have  $Q = 1$ ,  $(1/Q - 1) = 0$ . From the above we get

$$\Delta_i^2 = (Q_i - 1)^2/q_i^2 \quad (2)$$

The modified discrepancy index,  $\theta$ , may now be compared with the critical value  $\theta_0$  from  $\chi^2$  tables to test the match.

$$\theta = \sum_{i=1}^N \Delta_i^2 = \sum_{i=1}^N (Q_i - 1)^2/q_i^2. \quad (3)$$

when

$$Q \rightarrow 1, \Delta_i^2 \rightarrow D_i^2.$$

It may appear that when  $X_1$  and  $X_2$  are (presumed to be) normally distributed,  $D^2$  is  $\chi^2$  distributed, then  $\Delta_i^2$  cannot be  $\chi^2$  distributed. In fact "a Gaussian distribution may be inappropriate for measurements, such as chemical composition, which must be always non-negative, a functional transform whereby the new variate is brought into closer alignment with the Gaussian distribution may be used instead. The logarithm of the chemical composition could be used rather than the chemical composition itself<sup>2(a)</sup>. Indeed the log-concentration of elements in human hair has been found to be closely Gaussian<sup>2(b)</sup>. On the first presumption  $X_2 - X_1$  is a Gaussian variate with zero mean and standard deviation  $\sqrt{\delta_1^2 + \delta_2^2}$ . Now, if on the other hand  $\ln X_1$  and  $\ln X_2$  are admittedly better Gaussian distributed, and if the sample could stem from the alleged source,

$$\ln X_2 - \ln X_1 = \ln (X_2/X_1) = \ln \left( 1 + \frac{X_2 - X_1}{X_1} \right) \approx \frac{X_2 - X_1}{X_1} = \left( \frac{1}{Q} - 1 \right)$$

is a Gaussian variate with zero mean and standard deviation  $k' = q/Q$ , and  $\Delta_i^2$  is  $\chi^2$  distributed. The approximation involved is valid at lower discrepancies where the test for matching is sought.

It will now be shown that the use of  $c$  in place of  $\ln c$  (cf. Parker) does not make any significant difference where a critical examination is necessary. For large discrepancies, the difference in the crime sample and the alleged source is obvious; an inspection of data is sufficient. The use of  $c$  units makes evaluation of data less laborious.

Using  $c$  units, we have a series of measurements :

$$c_1 = \bar{c} + x_1, \dots, c_n = \bar{c} + x_n, \text{ where } x\text{'s can be}$$

+ve -ve, yielding the result:  $\bar{c} \pm \delta_c$  where  $\delta_c$  is the standard deviation, calculated using  $c$  units directly. To convert the measurements into  $\ln c$  units, we

$$\text{have, } \ln c_1 = \ln (\bar{c} + x_1) \approx \ln \bar{c} + x_1/\bar{c}, \text{ etc.,}$$

showing that  $\delta_{\ln c} \approx \delta_c/\bar{c}$  where  $\delta_{\ln c}$  is the standard deviation calculated using  $\ln c$  units. Parker's discrepancy index element,  $D_i^2$  using  $\ln c$  units, can now be readily shown  $\approx D_i^2$  using  $c$  units, at lower discrepancies.

$$D_i^2 = (\ln X_1 - \ln X_2)^2 / [(\delta_{c,1}/X_1)^2 + (\delta_{c,2}/X_2)^2]$$

can be shown, at lower discrepancies,  $\approx (X_1 - X_2)^2 / (\delta_{c,1}^2 + \delta_{c,2}^2)$ . Thus in Parker's eqn. (1) whether  $\ln c$  values or  $c$  values are taken, these reduce to the same form and magnitude at lower discrepancies, where the test is necessary.

**Alternative Method for Constructing a Discrepancy Index.**—The discrepancy quotient,  $Q$ , ( $Q \geq 1$ ) may be suitably modified to yield a minimum value,  $Q_{min}$ . Thus at a given chosen probability level

$Q_{min} = Q - t \cdot k$ , where ' $t$ '—times the standard deviation is subtracted on the basis of Student's  $t$  value for the given desired probability level and for the given degrees of freedom. Thus for a series of 10 measurements (9 degrees of freedom) for  $i$ -th attribute the probability of a chance deviation in  $Q$  not exceeding  $2.26 k$  is 95% ( $t = 2.26$ ). Having obtained  $Q_{min}$  values for each attribute, ( $Q_{min} \geq 1$ ), we have the alternative discrepancy index, which may now be denoted by  $\Gamma$ , simply given by :

$$\begin{aligned} \Gamma &= \prod_{i=1}^N Q_{min, i} = \prod_{i=1}^N (Q_i - t_i k_i) \\ &= \prod_{i=1}^N Q_i (1 - t_i \cdot q_i). \end{aligned} \quad (4)$$

$Q_{min}$  values  $\geq 1$  only are considered ; those working out to  $< 1$  are ignored, as these mean that there

is no significant difference in the values of the given attribute. Ideally,  $\Gamma_0$  for identity between the crime sample and the alleged source should be unity. Values of  $\Gamma$  in excess of unity would therefore indicate the extent of discrepancy between the two.

Application of the above criteria to typical literature data is given in Tables I to III. While  $\Gamma$  is well suited to the evaluation of data on chemical composition it will be apparent that in the evaluation of data on physical properties like density, refractive index, etc., in the event of high discrepancies (owing to very low  $q$ 's),  $\Gamma$  will not suitably reflect these. The discrepancy indexes  $c$  and  $\theta$  have therefore general applicability.

## 2. ASSESSMENT OF EVIDENTIAL VALUE

Once the questioned material is shown indistinguishable from the alleged source, the next consideration arises as to what significance or evidential value this agreement has. Let  $p_i$  be the probability of finding the level of the  $i$ -th attribute in the entire population similar to that in the alleged source then the probability of finding  $N$  uncorrelated attributes (which may be measured) in levels

similar to those in the alleged source is  $P_N = \prod_{i=1}^N p_i$ . The smaller the value of  $P_N$ , the more weighty is the evidence. The value of an attribute towards identification depends on "the ratio of the measurement error to the spread of the attribute over the population and also on the value of the sample measurement when referred to the peak of the frequency distribution"<sup>2(b)</sup>. In the case of normal distributions the probability  $p_i$  of finding the level of the attribute  $i$  in the entire population similar

to that in the crime material or the alleged source, for which the intrinsic variability of the material and the measurement errors are determined would simply be given by the ratio of areas under the respective distribution curves,  $a/A$ , where  $a$  is that under the source curve and  $A$  is that under the population curve. If the latter is plotted as  $\phi_x$  vs

$\sigma$  curve (Fig. 1) such that the normal distribution is valid:  $\phi_x = (1/\sqrt{2\pi}) \exp(-x^2/2)$  where  $x$  is measured in standard deviation  $\sigma$  units, we have, by definition, area under population curve (PQR, Fig. 1),  $A = 1$ . Therefore  $p_i = a$ , the area under the distribution curve for the source (say, ABC or DEF) which is properly constructed within the

FIG. 1. Construction of a typical normal distribution curve for the alleged source material (ABC or DEF) within that of the population (PQR).  $\phi_x$ ,  $t$  in  $\sigma_{\text{population}}$  units,  $\sigma_{\text{source}}/\sigma_{\text{population}} = 0.047$ ,  $-1.17, 0.1$  and  $0.14, +0.75, 0.2$  for curves ABC and DEF respectively.

The approximation in the above equation may be corrected for by utilizing :

$$p_i = 2.51 \phi_{x,i}^* (\sigma_{\text{source}}/\sigma_{\text{population}})_i \quad (5)$$

with benefit to the accused.  $\phi_{x,0}$  ( $\phi$  corresponding to  $\sigma = 0$ ) = 0.3989, is equivalent to area.  $A = 1$  (vide supra). Therefore, area equivalent to  $\phi_{x,i}^* = (1/0.3989) \phi_{x,i}^* (\sigma_{\text{source}}/\sigma_{\text{population}})$ , the same as in eqn. (5).

*Illustration.*—The calculation of  $P_N$  for a sample human hair<sup>2(b)</sup> is illustrated in Table IV. The analysis utilizing eqn. (5) would thus reveal, granted that our assumption of (log —) normal distribution over the population is valid and that the attributes are uncorrelated, that there is 1 in  $\sim 10^7$  chance of finding such hair in the population in question, with levels of the ten attributes in question similar to those in the given sample. The magnitude of  $P_N$  is indicative of the uniqueness of the given physical evidence material. It is an attempt to quantitate the evidential value.

TABLE IV

Uniqueness of crime material—Human hair in "control" sample<sup>2(b)</sup>

| Attribute | $\frac{\mu_{\text{control}} - \mu_{\text{population}}}{\sigma_{\text{population}} = t}$ | $\phi_{x,i}^*$<br>(corresponding to $t$ ) | $p_i = 2.36 \phi_{x,i}^* \left( \frac{\sigma_{\text{control}}}{\sigma_{\text{population}}} \right)$ |
|-----------|---|---|---|
| Na        | 0.442   | 0.362                                     | 0.201   |
| Sb        | 0.855   | 0.277                                     | 0.284   |
|           | Likewise for Cl, Mn, I, Cu, Br, Au, Hg, Zn  |   |   |

$$P_N = 1.1 \times 10^{-7} \text{ (Eqn. 5)}$$

$$P_N = \prod p_i = 0.58 \times 10^{-7}$$

population curve. Evaluate  $t = |\mu_{\text{population}} - \mu_{\text{source}}| / \sigma_{\text{population}}$ , where  $\mu$  is the mean value. The crime material or the source is therefore  $t$  units of population-standard deviations removed from the population mean value. Construct a normal curve on the ordinate at  $t$  converting  $\sigma_{\text{source}}$  into  $\sigma_{\text{population}}$  units, by the factor  $(\sigma_{\text{source}}/\sigma_{\text{population}})$ . The area under the source curve,  $a$ , can be evaluated as  $a \approx \phi_{x,i}^*$  (H.I.B.W.) where  $\phi_{x,i}^*$  is the ordinate corresponding to the  $t$  value (e.g., Bb or Ee) which can be directly read from the normal error curve tables. The half-intensity band width, H.I.B.W., (e.g.,  $hh'$  or  $h'h'$ ) =  $2.36 (\sigma_{\text{source}}/\sigma_{\text{population}})$  for the source curves. H.I.B.W. =  $2.36 \sigma$  units for any normal curve. We have, therefore,

$$p_i = a_i = 2.36 \phi_{x,i}^* (\sigma_{\text{source}}/\sigma_{\text{population}})_i$$

## XVII INTERNATIONAL CONGRESS OF MATHEMATICIANS

**T**HE International Congress of Mathematicians is held once every four years. The XVII Congress met at the University of British Columbia, Vancouver, Canada, from August 21–29, 1974. The last Congress was held in Nice France in 1970. The Congress was attended by about 3000 mathematicians from all over the world. A few of its sessions were also held at the Universities of Victoria and Simon Fraser.

The Conference was inaugurated on August 21 by Lieut. Governor of British Columbia followed by addresses of the President and the Mayor of Vancouver at the Queen Elizabeth Theatre. This year only two gold medals were awarded—one to Enrico Bombieri of Pisa University, Italy, for number theory, and the other to David B. Mumford of Harvard University for Algebraic Geometry.

During the Conference seventeen expository addresses, 160 short communications and 750 Research papers were presented. About 50 Indians of whom 40 were already residents abroad presented their papers at the Congress. They included C. R. Rao, V. K. Patodi, V. S. Varadarajan, B. R. Seth, R. S. Mishra, H. R. Gupta, M. K. Singhal, P. Puri, M. N. L. Narasimhan, P. N. Kaloni, B. D. Agrawal, S. M. Sah, V. M. Soundalgekar.

The general lectures dealt with potential theory, Fourier analysis, partial differential equations, eigenvalues of the Laplacian and invariants of manifolds, tidal energy, quantum field theory, transversal theory, mathematical theory of economic equilibrium, theory of buildings, number theory and uniform approximation by holomorphic functions. The general lectures were given in the morning and the presentation of papers was done in a number of sections in the afternoon. Those dealing with mathematical physics and mechanics continued for five days. There was good interest shown in bi-mathematics, history and education. There were a number of sessions on topology, group theory, complex and real analysis, partial differential equations, logic and foundations and functional analysis.

The resurgence of the study of geometrical bodies inside a manifold was discussed by Dennis Sullivan. The qualitative study of dynamical systems produces inside one manifold interesting compact subsets, families of intertwined non-compact submanifolds, geometrically defined measures and currents, with homological interpretations and relationships. A. G. Vitushkin showed that recent advances in uniform approximations of holomorphic functions mainly consist in the improvement of integral representa-

tions, estimation of the solutions and the construction of concrete examples to correct hypotheses.

G. F. D. Duff dealt with the partial differential equations of the tidal motions which form a symmetric hyperbolic system in two space dimensions with a monotone non-linearity in a variable domain. C. Radhakrishna Rao gave a general survey of recent results on characterization problems and their applications to testing of hypothesis, estimation of parameters, inference on unobservable structural variables and specification problems. An account of Harish Chandra's work on harmonic analysis on real semisimple Lie group with special emphasis on the Plancherel formula was given by V. S. Varadarajan. He also discussed matrix coefficients and the theory of eigenfunction expansions, infinitesimal theory of representations and intertwining operators for irreducible representations. Masahisa Inoue gave new examples of surfaces with affine structures.

B. R. Seth showed that the transition region may be interpreted as : (i) an asymptotic subspace ; or (ii) a criticality or singularity of the differential manifold defining the medium ; or (iii) a change of group symmetry ; or (iv) a singular transformation matrix. It is found that transition fields are sub or super-harmonic and are characterised by spin, rotation or vorticity effects. M. N. L. Narasimhan and A. C. Eringen gave balance laws governing the flow of heat-conducting nematic liquid crystals. A generalized form of the Clausius-Duhem inequality gives the effects of heat conduction. Gilbert Strang proved that in the non-linear applications of the Finite Element Method the first step improves the error involved from  $o(h)$  to  $O(h^{3/2})$ ,  $h$  being the mesh-width.

R. Arthur Knebel generalised Kleene's theorem on automata to universal algebra. R. Padmanabhan proved that any uniquely complemented lattice belonging to the class K is distributive.

Michael Doob showed that several classes of graphs are magic.

Hansraj Gupta dealt with a number of Magic partitions.

V. Krishnamurthy showed that the counting of  $T_0$ -topologies may be reduced to the counting of a special type of bichromatic trees.

Wolfgang Weil communicated the result that an arbitrary convex body in three dimensions of constant brightness and of constant width must be a ball.

B. R. SETH.

## OBITUARY

PROFESSOR LAKSHMISWARA RAMA RAO, M.A., F.G.S., F.N.A., F.A.SC.

(1896-1974)

By

PROF. S. SAMBE GOWDA

*Department of Geology, Central College, Bangalore*

**I**N the death of Prof. Lakshmiswara Rama Rao on November 11, 1974 at the age of seventy-eight the country has lost a great *acharya*, a renowned geologist, and an able administrator of cardinal virtues.

After declining the offer by the Government to join the Civil Service soon after coming out successfully with the 'CROMARTY PRIZE' at the degree examination of the Madras University in 1917, he took to his teaching career at the Central College and never regretted for the same. He perfected the art of teaching with his inborn talent and no superlatives will suffice to describe him as a teacher. Prof. Rao took to his research in right earnest at the very beginning of his career on the Upper Cretaceous rocks found along the east coast in South India and continued till to the last minute of his life, for over half a century! The discovery of identifiable remains of Dinosaurs, the discovery of microfossils such as Radiolarians in the rocks of the Utatur division, the algal genus *Archaeolithothamnium* in the Niniyur rocks, the identification of a larger foraminifer in the Pondicherry rocks as *Discocycliella* formed the main lines of his early investigations.

In his Presidential address to the Geology section of the Indian Science Congress Association in 1940, he reviewed the investigations on "Cretaceous-Tertiary Boundary" and the topic became a subject of investigation in all the continents by leading geologists. He presided over the section on Cretaceous-Tertiary Boundary at the 22nd International Geological Congress in New Delhi, and his review appeared in a special publication of the Mysore Geologists' Association. He was invited in 1972 on behalf of the International Union

of Geological Sciences by the Soviet Academy of Sciences to take part as a member of the Commission on Cretaceous-Tertiary Boundary, a fitting tribute to his sustained and serious pursuit of his chosen and choicest investigation! This coincided with the award of a medal by the Asiatic Society of Bengal in the same year.

Professor Rama Rao laid the foundation for micropalaeontological research in India. Thanks to his vision, the country has come of age in this field. It was a great day for him when the First Indian Colloquium on Micropalaeontology was inaugurated by him in Bangalore in 1971. His ambition was to organise an association of micropalaeontologists and it would be a fitting memorial to him if this Association is established on a permanent basis.

Prof. Rao played a leading and vital role in the founding of almost all the prestigious and national scientific associations, academies and the institutes including the *Current Science Association*. A special mention, however, must be made here of the great effort he made in founding the Geological Society of India and in steering the same to its present status and in bringing credit to its journal which he edited till he breathed his last.

As the Principal of Central College and as the Head of the Department of Geology, Central College with a long innings Prof. Rao has left his footprints of perfection, purity, unbiassed approach, great integrity and unimpeachable acts.

May his soul rest in peace and may his spirit inspire all those who want to work for the cause of Geology.

## LETTERS TO THE EDITOR

### DISSOCIATION ENERGY OF ALKALI HALIDE MOLECULES\*

#### ABSTRACT

Expressions for the dissociation energy have been obtained by consideration of three logarithmic potential energy functions suggested recently. The values of the dissociation energies of twenty diatomic alkali halide molecules have been calculated with the help of these expressions. The results obtained are encouraging.

**Key Words.**—Electron affinity, Ionisation potential, Binding energy, Force Constant.

In actual practice none of the ionic molecules is transformed to the separate ions under any observable conditions since ionisation energy always exceeds the electron affinity. The lowest ionisation energy, that of cesium  $377 \text{ kJ mol}^{-1}$ , is higher than the highest electron affinity,  $356 \text{ kJ/mole}$ , that of chlorine. For most compounds the difference is much greater. The gaseous atoms are, therefore, at room temperature, always more stable than the gaseous ions. Thus the binding energy represents only the hypothetical values for the unrealizable processes, whereas dissociation energy represents the more realistic values. The dissociation energy of ionic molecules is of much interest. Up to the present time only limited attempts have been made<sup>1</sup> to calculate dissociation energy using the interaction potential energy functions. The potential functions used previously have been discredited by Thakur<sup>2</sup> and Dobbs *et al.*<sup>3</sup>. Thakur<sup>2,4,5</sup> has suggested three logarithmic forms of the interaction potential functions which have been widely used<sup>6</sup> to calculate several properties of the ionic salts. In the light of these facts and the fact that the values of  $r_e$ ,  $E$  and  $k_e$  used by Tandon<sup>1</sup> were not so accurate it is worthwhile to recalculate the dissociation energies. The present note is concerned with the theoretical computation of the dissociation energies of alkali metal halides using more realistic interaction potentials and molecular constants known to a higher degree of accuracy.

The new potential energy functions are :

$$U(r) = -\frac{e^2}{r} + C \log \left[ 1 + \frac{p}{r^4} \right] \quad (1)$$

$$U(r) = -\frac{e^2}{r} + B \log \left[ 2 + \frac{b}{r^2} \right] \quad (2)$$

$$U(r) = -\frac{e^2}{r} + D \log \left[ 4 + \frac{d}{r} \right] \quad (3)$$

where  $C$ ,  $p$ ,  $B$ ,  $b$ ,  $D$  and  $d$  are potential parameters and the rest terms have their usual meanings. The

potential parameters may be calculated using molecule stability and force constant conditions in the conventional<sup>2,4,5</sup> way. Thus binding energy  $D_i$  is given by

$$D_i = -U(r_e) \quad (4)$$

and dissociation energy  $D_e$  is given<sup>2,4,5</sup> by

$$D_e = E - I + D_i \quad (5)$$

where  $E$  is the electron affinity of halogen atoms and  $I$  is the ionisation energy of alkali metals.

The application of these conditions to potential functions (1)–(3) yields :

$$D_e = E - I + \frac{e^2}{r_e} \left[ 1 - \left( \frac{r_e^4 + p}{4p} \right) \times \log \left( 1 + \frac{p}{r_e^4} \right) \right] \quad (6)$$

$$D_e = E - I + \frac{e^2}{r_e} \left[ 1 - \left( \frac{2r_e^2 + b}{2b} \right) \times \log \left( 2 + \frac{b}{r_e^2} \right) \right] \quad (7)$$

$$D_e = E - I + \frac{e^2}{r_e} \left[ 1 - \left( \frac{4r_e + d}{d} \right) \times \log \left( 4 + \frac{d}{r_e} \right) \right] \quad (8)$$

The values of the molecular parameters used in calculation have been taken from various sources of the literature<sup>7–11</sup> and are listed in Table I.

Table II presents the calculated values of  $D_e$  from Equations (6)–(8). The experimental values of  $D_e$  in Table II are of Gaydon<sup>12</sup>. The agreement between the theoretical and experimental values is fair. Thus we find that the new potential functions, which give good values of several constants, yield good values of dissociation energy also.

The author thanks the Government of India for the award of National Merit Scholarship and CSIR, New Delhi, for research assistanceship.

### X-RAY, DIELECTRIC AND RESISTIVITY STUDIES OF BaGeO<sub>3</sub>

THE  $A^{2+}B^{4+}O_3$  compounds with  $Ge^{4+}$  as B ion seem to have attracted very little attention though some of these have been found to exhibit interesting properties<sup>1,2</sup>. Here we report the structural and electrical properties of BaGeO<sub>3</sub>.

*Preparation of the compound.*—The two oxides BaO–GeO<sub>2</sub> (purity above 99.99%) are mixed in 1:1 molar proportion under acetone. The mixture was then dried in air. It was heated in a platinum crucible for about 50 hours at 750° C. The mass was then slowly cooled to room temperature. BaGeO<sub>3</sub> is found to be a pinkish coloured powder. The compound is not hygroscopic.

*X-Ray study.*—The structure of the compound was investigated using 114.6 mm diameter Debye-Scherrer camera and filtered CuK<sub>α</sub> radiation. A comparison of the  $d$  values and the structure of the compound synthesised by us with those reported earlier<sup>3</sup> show a clear disagreement. BaGeO<sub>3</sub> is found to have an orthorhombic cell with  $a = 6.09$  Å,  $b = 4.85$  Å, and  $c = 6.52$  Å. The observed and calculated  $d$  values are given in Table I. The

W: Weak, M: Medium, S: Strong, V.W.: Very weak.

absence of GeO<sub>2</sub> lines as well as the presence of new unit cell indicates the formation of the compound. The difference between the structure of BaGeO<sub>3</sub> reported earlier and that reported here is

probably due to the prolonged heating at a lower temperature during its preparation<sup>1</sup>.

Goldschmidt<sup>5</sup> has shown that compounds with general formula  $A^{2+}B^{++}O_3$  possess a cubic perovskite structure if a tolerance factor defined by

$$R_A + R_O = t \sqrt{2(R_B + R_O)}$$

has values between 0.77 and nearly one and a somewhat larger range for distorted perovskite structures.  $BaGeO_3$  with  $t = 1.007$  would therefore be expected to possess similar structure. Hence intensity calculations for all the observed reflections were carried out assuming orthorhombic  $BaTiO_3$  type structure (Bmm2). Very little agreement is found between the calculated and the observed intensities indicating that the structure of  $BaGeO_3$  is different from that of  $BaTiO_3$  (perovskite type).

**Resistivity and Dielectric study.**—The compound was pressed into pellets for studying its electrical properties. The finely ground powder of the compound was mixed with a little binder (PVA) and pressed into pellets of 1 cm diameter and 2 mm thickness under pressure of 10 ton/Sq inch in a hydraulic press. The pellets were then heated to 200° C for a few hours in a furnace to remove the binder. The temperature was then raised to 750° C and maintained there for six hours and then slowly lowered to room temperature. The dielectric constant at 1 KHz and  $d c$  resistivity of the pellets were measured by Marconi Universal Bridge type TF 868/1 and B.P.L. meg-meg-ohm-meter type RM 160/3 respectively. The variation of dielectric constant with temperature is shown in Fig. 1 and that of resistivity in Fig. 2. The resistivity of  $BaGeO_3$

FIG. 1. Variation of  $\epsilon'$  with temperature.

shows a marked anomaly at 32° C but the dielectric constant shows an anomaly at a slightly lower

temperature. The anomalous behaviour is observed in all the pellets on heating but not reproduced in the cooling cycles. Identical results were obtained on repeating the measurements a number of times. The response to heating is spontaneous. This type of behaviour is also reported in  $RbNO_3$ <sup>6</sup>. The detailed investigations of the nature of anomaly, space group, and high temperature phase are in progress.

FIG. 2. Variation of resistivity with  $1000/T$  ( $K^{-1}$ ).

**SYNTHESIS OF SOME NEW ARYL- AND  
ARYLOXYALKYL-N-(5-NITRO-2-FURYL)-  
CARBAMATES AS POTENTIAL  
ANTIMICROBIAL AGENTS**

5-NITROFURAN derivatives are well known for their antibacterial<sup>1</sup> activity. Also many carbamates have been found to possess diverse types of biological activity including antifungal<sup>2</sup> and anthelmintic<sup>3</sup> activities, etc. No biological activity is described for alkyl-N-(5-nitro-2-furyl) carbamates known in literature<sup>4,5</sup>. Furthermore, the presence of aryloxy groups in many antimicrobial agents<sup>6</sup> seems to be their important feature. Fifteen new aryl- and aryloxyalkyl-N-(5-nitro-2-furyl) carbamates (I and II) have been synthesised with a view to evaluate their antifungal and antibacterial activities.

5-Nitro-2-furyl azide was made following the method of Singleton and Edwards<sup>7</sup> by treating an ethereal solution of 5-Nitro-2-furoyl chloride with aqueous sodium azide at 0–5° C when it separated out as an yellow crystalline solid. I.R. (Nujol, cm<sup>-1</sup>): 2140 s (N=N=N) and 1680 s (C=O). The final carbamates were obtained by condensing various phenols and aryloxyalkanols with 5-nitrofuryl isocyanate obtained *in situ* from above 5-nitrofuroyl azide.

In a typical experiment for the preparation of the aryl carbamates, 5-nitro-2-furoyl azide (0.01 moles) in dry benzene (25 ml) was heated for 4 hours at 75° to liberate 5-nitro-2-furyl isocyanate (small quantity of black powder separated out due to

polymerisation). Phenol (0.011 moles) in dry benzene (25 ml) was added to 5-nitro-2-furyl isocyanate, thus obtained, and heating was further continued for 6 hours. Ether (100 ml) was added to the cooled reaction mixture, organic layer washed with 10% hydrochloric acid followed by water and dried (Na<sub>2</sub>SO<sub>4</sub>). Removal of the organic solvent gave brownish yellow solid which was taken in benzene and chromatographed over silica gel. Elution with benzene afforded phenyl-N-(5-nitro-2-furyl) carbamate as yellow shining needles, which was further purified by recrystallising from benzene-petroleum ether (40–60° C).

The aryloxyalkyl carbamates were prepared by heating the azide and aryloxyalkanols directly without a solvent at 70° till the evolution of nitrogen ceased. The products were worked up as usual.

All the carbamates showed characteristic I.R. absorptions (Nujol, cm<sup>-1</sup>): 3230 m (NH) and 1720 s (ester). Table I gives the details of various compounds prepared together with their melting points, elemental analyses and percentage yields. All compounds were recrystallised from benzene-petroleum ether (40–60°).

All the fifteen carbamates were tested *in vitro* for antifungal activity by agar dilution assay method<sup>8</sup> and for antibacterial activity by serial dilution tube method<sup>9</sup> using various pathogenic test organisms. Some of the compounds were found to possess moderate activity as shown in Table II.

### INFLUENCE OF SOLVENTS ON THE CHELATION IN BENZOIN AND METHYL MANDELATE

INTRAMOLECULAR hydrogen bonding in six membered chelates as formed in salicylaldehyde, methyl salicylate, 2-hydroxy acetophenone and enols of  $\beta$ -diketones has been studied earlier<sup>1</sup>. The intramolecular hydrogen bonding leading to the formation of five membered chelate, however, received little attention.

In this communication, evidence for chelation in benzoïn and methyl mandelate is furnished. With a view to studying the influence of solvents on chelation the pmr spectra of these compounds have been recorded on Varian A. 60 D in  $\text{CS}_2$ ,  $\text{CDCl}_3$ , DMSO, DMF, acetone and in the presence of traces of trifluoroacetic acid and methanol using TMS as internal standard at 37°C. The

concentrations of the solutions used are of the order of 0.1 molar. The results are presented in Table I.

TABLE I

*CH and OH chemical shifts of benzoin and methyl mandelate in different solvents*

TFA = Trifluoro acetic acid

DMF = Dimethylformamide

DMSO = Dimethylsulphoxide

The spectra of benzoin and methyl mandelate were reported earlier<sup>2,3</sup> but no study has been made in regard to chelation in these compounds. Both the compounds are found to exhibit doublets ( $J = 6.0$  Hz) for proton signals of OH and CH of CHOH group. This is in contrast to the earlier report<sup>2</sup> where singlets were reported for OH and CH protons. The splitting of OH and CH signals may be due to coupling between them. In presence of D<sub>2</sub>O, trifluoroacetic acid and methanol, the OH signals vanished and the CH signals collapsed into singlets. Such a collapse of the fine structure of the proton signals due to chemical exchange was reported earlier in the case of methanol<sup>4</sup>. In the presence of acids or bases the CH<sub>3</sub> doublet of methanol collapses into a singlet due to rapid OH proton exchange. The CH<sub>3</sub> signal, however, appeared as a doublet in the presence of sufficient amount of acetone.

On hydrogen bond formation between the  $\text{C}=\text{O}$  (acetone) and  $-\text{OH}$  (methanol) the resident time of the OH proton in the hydroxyl group increases when coupling with methyl group becomes possible. The doublet signals for CH of  $-\text{CHOH}$  in benzoin and methyl mandelate therefore suggest bonding between OH and  $\text{C}=\text{O}$ , leading to the formation of a five membered chelate. This is also reflected in the

downfield shift of OH proton in CDCl<sub>3</sub> of benzoin (4.57  $\delta$ ) and of methyl mandelate (3.35  $\delta$ ), as compared to the OH proton in benzyl alcohol (2.43  $\delta$ )<sup>5</sup>.

The relative insensitivity of the OH proton signals to the changes in concentration further support the formation of intramolecular hydrogen bonding. The downfield shift of the OH proton in these compounds is not so great as in other chelate compounds, viz., salicylaldehyde, 2-hydroxy acetophenone and enols of  $\beta$ -diketones. Chelation in these compounds, therefore, appears to be weak. The weak chelation may be due to the absence of conjugation in the chelate ring, as found in the compounds mentioned above. The larger downfield shift of OH proton in benzoin as compared to that in methyl mandelate may be due to greater electron donating ability of the oxygen of the ketonic  $\text{C}=\text{O}$  than that of the ester  $\text{C}=\text{O}$ . The lone pair electrons on the oxygen of the ketonic  $\text{C}=\text{O}$  approach the OH proton more closely and repel greatly the electron which is in the neighbourhood of the hydrogen nucleus and therefore reduce the diamagnetic shielding of that nucleus by its own electrons and increase the paramagnetic deshielding<sup>6</sup>.

The influence of solvents on the chemical shifts of CH and OH protons of benzoin and methyl mandelate is rather interesting. The signals of both the protons remain as doublets indicating the absence of OH proton exchange as noticed in the presence of D<sub>2</sub>O, trifluoro acetic acid and methanol. With the increase in polarity of the solvent from CS<sub>2</sub> to DMSO the OH signals in general move to lower fields, the shifts being larger in  $n$ -donor solvents like DMSO, DMF and acetone.

Although the OH chemical shifts of benzoin and methyl mandelate are different in CDCl<sub>3</sub> and CS<sub>2</sub> both of them have almost the same value either in DMF and DMSO. This may happen when the OH groups of the two compounds are bonded to the same donor. In DMSO and DMF, the chelation may be ruptured and intermolecular hydrogen bonds may be formed with more basic solvent molecules as shown in Fig. 1.

FIG. 1

This view is in agreement with an earlier finding<sup>7</sup> that the chelation in salicylaldehyde is disrupted with DMSO leading to the formation of an intermolecular hydrogen bonding.

# ECOPHYSIOLOGY OF A HOST-PARASITE SYSTEM: EFFECT OF INFECTION OF A PARASITIC COPEPOD, *LERNAEA HESARGATTENSIS* ON THE OXYGEN CONSUMPTION OF THE FISH, *LEBISTES RETICULATUS* PETERS)

Work on the physiology of copepods, especially of the parasitic forms, is wanting<sup>1</sup>. A new species of a parasitic copepod *Lernaea hesargattensis*, infecting the cyprinodont fish *Lebistes reticulatus*, has been recently described<sup>2,3</sup>. The adult female parasites are found to be firmly embedded in the muscular tissue of the host and thus obtain their nutritional requirement.

One of the vital ecological factors affecting the survival of fish is the availability of oxygen in the aquatic habitats and the oxygen consumption of the fish is a direct index to its metabolic rate and food requirement<sup>4</sup>. Hence, in the present paper, the effects of infection of *L. hesargattensis* on the oxygen consumption of the fish *L. reticulatus* is described.

The test fish were collected from the fish ponds of Hesarghatta, near Bangalore. The fish were separated into the following experimental series: (1) Normal, (2) infected, with the parasite intact and (3) infected, with the parasites removed. Oxygen consumption of all these fish were estimated for males and females separately, using the modified Winkler's method<sup>5</sup>. In many of the infected fish, at the region of penetration of the parasite, certain tissue damage and inflammation around the area was observed. This reaction was local and did not extend beyond the area of infection. Similar local

reactions were recorded in salmonids due to infection by the leach *Piscicola salmonisica*<sup>6</sup>.

Table I represents the average values of oxygen consumed by males and females of the experimental series. A normal male fish consumed  $0.2685 \pm 0.051$  cc of oxygen/gram body weight/hour. During the same period the infected fish consumed as much as  $0.3314 \pm 0.139$  cc of oxygen/gram body weight.

TABLE I

*Effect of infection of the copepod parasite Lernaea hesargattensis on the oxygen consumption of male and female Lebistes reticulatus. Each value represents the mean of 6 experiments*

| Material                   | Sex    | Body weight (mg) | Oxygen consumed/g body weight/hour (cc) |
|----------------------------|--------|------------------|---|
| Normal                     | Male   | 196.80           | 0.2685                                  |
|                            |        | $\pm 13.83$      | $\pm 0.051$                             |
| Controls                   | Female | 264.27           | 0.7725                                  |
|                            |        | $\pm 22.67$      | $\pm 0.320$                             |
| Infected, with parasite    | Male   | 174.87           | 0.3314                                  |
|                            |        | $\pm 12.78$      | $\pm 0.139$                             |
|                            | Female | 329.05           | 0.8981                                  |
|                            |        | $\pm 26.92$      | $\pm 0.084$                             |
| Infected, without parasite | Male   | 114.58           | 0.2608                                  |
|                            |        | $\pm 8.94$       | $\pm 0.159$                             |
|                            | Female | 330.20           | 0.6614                                  |
|                            |        | $\pm 31.22$      | $\pm 0.332$                             |

The corresponding value for normal and infected females were  $0.7725 \pm 0.320$  and  $0.8981 \pm 0.084$  cc of oxygen/gram body weight/hour, respectively. The higher consumption by female *Lebistes*, despite a larger body weight when compared to males, may be due to the fact that these experiments were conducted during March 1973 when the laboratory water temperature was 32°C, five degrees more than the temperature at which the males were experimented (November, 1972).

In both male and female *Lebistes*, when the parasites were removed, the oxygen consumption dropped back almost to the normal values. In the males, on removal of the parasite, the fish consumed  $0.2608 \pm 0.159$  cc of oxygen/gram body weight/hour and in the females, the corresponding value was  $0.6614 \pm 0.332$  cc. Moreover, the oxygen consumed by the parasite alone (after it was removed from the host's tissue) was found to be negligible. Hence, this increased oxygen consumption of the infected *Lebistes*, irrespective of the sex of the fish, can be attributed to a 'stress reaction' due to parasitic infection of the copepod.

The percentage increase in the oxygen consumed, from the normal to infected males, was 20.42 while in females this increase was slightly less (16.30%).

A respiratory increase of 5% of the host's normal metabolic rate was observed in the sculpin *Myoxocephalus scorpius* infected by the leech, *Malmiana nuda*<sup>7</sup>. Even here, the increase was attributed to the increased rate of blood and tissue formation and to stress caused by the mechanical irritation of the feeding leeches. Thus, it may be surmised that though large respiratory increases may not be observed with smaller burdens of parasitic infection under natural conditions, oxygen deficient waters and/or heavy parasitic infections may be detrimental to the fish.

Further work on the ecophysiology of this host-parasite system is in progress.

The authors are grateful to late Professor K. Pampapathi Rao for his valuable suggestions and discussions during the present study and to Dr. A. R. Kasturi Bai, Head of the Department of Zoology, for encouragement.

#### CHANGES IN CALCIUM AND PHOSPHATE LEVELS IN THE BONES OF BABY AND ADULT LORIS, *LORIS TARDIGRADUS*

THE extracellular constituent of bones is a system of collagen and calcium phosphate. The latter has a structure identical or similar to hydroxyapatite,  $\text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2$ . It contains crystalline and amorphous fractions, the crystalline ones, increasing with age<sup>1</sup>. Concurrently, the Ca/P ratio shifts towards higher calcium values. The major constituent of bone is collagen. Its content amounts to approximately one-third of the total bone mass<sup>2</sup>.

Various substitutions and ion exchanges leading to the hydroxyapatite structure occur during maturation of human bones<sup>3,4</sup>. In man, it is also known

that the Mg content is highest in the bones of the youth which, as the age progresses, is replaced by the deposition of  $\text{Ca}^{5+}$ . This process of ion exchange is known as 'slagging'.

Whether such ion exchanges or slagging occurs with age in the slender loris, a prosimian, has been investigated in this paper.

Marrow free and oven dried humerus, femur and parietal bones of baby (1 month old) and adult (2 years old) were weighed and dissolved in 100 ml of 0.6 N HCl and the extract was analysed for calcium, magnesium, phosphorus and non-protein nitrogen. Calcium of the bone extract was precipitated as oxalate and titrated with standard potassium permanganate following the method of Clark and Collip<sup>6</sup>. After removal of calcium, magnesium of the extract was precipitated as magnesium ammonium phosphate according to Denis<sup>7</sup>. The resultant phosphate was estimated by Fiske-Subba Row method<sup>8</sup>. The bone extract was deproteinized with 5% trichloroacetic acid and the phosphorus of the protein-free filtrate was estimated according to Fiske-Subba Row<sup>8</sup>. The non-protein nitrogen (NPN) of the extract was determined by micro-Kjeldahl method as described by Oser<sup>9</sup>.

Analysis of bone extract revealed that the inorganic constituents varied with age and the bone. Calcium content significantly increased in the parietal bones but decreased in the femur during aging; phosphorus increased in the humerus in contrast to the femur and the parietal but the nitrogen content decreased in general, on aging.

In mammals (including man), the magnesium content of the bone is very low<sup>5</sup>, but in baby and adult loris it is higher than in other mammals. Magnesium, however, decreased in all bones on aging (Table I). In loris, blood also contains a high magnesium content<sup>10</sup> which might account for the high magnesium content in the bone. Long bones showed a lower and the parietals a higher phosphorus content in comparison with other mammals.

The theoretical molar ratio (Ca/P) for hydroxy apatite is 1.667 which differed with age and individual bones of loris (Table II); it increased on aging in the parietals and the femur in contrast to humerus. The ratios relatively higher than the theoretical ratio (Table II) probably indicate that calcium occurs in forms other than hydroxy apatite also. Molar ratios Ca/P, Mg/P and Ca/Mg (Table II) indicated that calcium might exist in different forms like calcium carbonate, in addition to its occurrence as hydroxy apatite. The high magnesium and low phosphorus contents of baby bones suggest the occurrence of a low hydroxy apatite content in young bones.

### OBSERVATIONS ON THE SCALES OF THE SHORT-FINNED EEL, *ANGUILLA BICOLOR* McCLELLAND AND THEIR UTILITY IN AGE DETERMINATION

It is well known that scales of fishes are of value in determining the age and growth of fishes. Several authors (Lee, 1920; Van Oostern, 1929; Walford and Mosher, 1943; Seshappa and Bhimachar, 1951; Jhingran, 1957; Seshappa, 1958 and Rao, 1961) have determined the age of various species of fishes based on the number of rings found on the scales. Pantulu (1956) has stated that scales could be used in estimating the age and not growth of the eel, *Anguilla bengalensis* Gray. In 1971 experimental eel culture was undertaken at the Regional Centre of Central Marine Fisheries Research Institute, Mandapam Camp, to develop a suitable method of culturing the short-finned eel, *Anguilla bicolor* McClelland. During the course of the experimental culture the scales of the cultured eels were studied to ascertain whether there is any correlation between the number of rings present on them and the age of eels. The results obtained in this study are reported here.

About 200 elvers of an average length of 100 mm were collected near the closed sluice gates of Srivaikundam anicut on the river Tambraparni near Tuticorin in October 1971, transported to Mandapam Camp and reared in running water tanks. They were fed daily twice with minced clam meat and fish flesh. The water temperature in the experimental tank varied between 28° and 30° C. The size attained by the cultured eels at the end of one year exhibited a wide range of 125 mm to 500 mm and the average size was 350 mm in total length and 106 gm in weight. For the present study scales were examined from cultured eels measuring 128 mm, 153 mm, 283 mm, 363 mm, 388 mm, and 500 mm in total length. Scales were removed from the area midway between anus and tip of tail on either side of the lateral line. 10 to 20 scales were examined from each eel. In this investigation scales having maximum number of rings alone were taken into considera-

tion as they are believed to represent the correct age of eels (Gemzoe, 1904; Frost, 1945 *a* & *b*).

The scales of eels are microscopic, very thin, flat and elongate-oval in shape and are embedded in the skin at right angles to each other (Pl. 1 A). They do not overlap but are "placed in individual sacs in the dermal tissue with no connection with the epidermal coverings" (Waly, 1940). The scales are composed of concentric rows of oval, round or polygonal head-like loculi.

PLATE 1. A, A portion of the lateral body surface of *Anguilla bicolor* McClelland, showing the disposition of scales. The lateral line also may be seen in the photograph; B, Scale of 128 mm long eel showing no ring; C, Scale of 153 mm long eel showing no ring; D, Scale of 283 mm long eel showing one ring; E, Scale of 363 mm long eel showing two rings; F, Scale of 388 mm long eel showing three rings; G, Scale of 500 mm long eel showing four rings.

Photomicrographs of scales, collected from eels of different sizes are shown in Plate 1 B-G. It may be seen that there are no rings on the scales collected from 128 mm and 153 mm long eels, whereas in 283 mm, 363 mm, and 500 mm long eels the

scales have one, two, three and four rings respectively. These results may lead to the conclusion that 283 mm, 363 mm, 388 mm, and 500 mm long eels are one, two, three and four years old respectively. It may be pointed out here that for this study scales were collected from eels reared in running water tank and though the eels ranged from 128 mm to 500 mm in total length, all of them were of the same age, as they had grown to these sizes from elvers during one year period. But their scales show varying number of rings. These observations clearly indicate that there is no relationship between the number of rings found on the scales and the age of eels. In the light of the above finding, the view so far held that the rings found on scales are annual in character and are indicative of age of fish, does not hold good for *A. bicolor*. In the present investigation the eels were reared in an environment where there were no marked changes either in the availability of food or temperature, which are normally believed to be responsible for formation of rings on scales. Therefore the causative factor for the formation of rings on scales is not clear.

Based on length frequency data and scale readings Pantulu (1956) has estimated age of *Anguilla bengalensis*. According to him the respective average length of I to V year old eels, as estimated from length frequency are 210 mm, 265 mm, 331 mm, 441 mm and 507 mm and as calculated from scale readings are 183.5 mm, 249.5 mm, 340 mm, 447 mm and 516.6 mm. Since there is a close agreement in the estimates of age calculated by the two methods, he stated that scales could be utilized for estimating the age of *A. bengalensis*.

The present experimental culture of *A. bicolor*, an allied species of *A. bengalensis*, has clearly shown that there is a wide range in the length of eels of same age and that there is no relationship between the number of rings present on the scales and age of eels. Bertin (1956) has also stated that measurement of length or weight cannot be used to determine the age and growth of an eel, as it would risk an error of one to five years either way. Therefore it may be stated that in the case of eels any estimate of age arrived at by length frequency method and scale readings is likely to be erroneous. The only reliable method of determining the age of eels is by making direct observations on the rate of growth through rearing.

### COMMON ANTIGENS IN HOST-PARASITE RELATIONSHIP\*

It has been shown in mammalian systems, that antigenic closeness between a host and a parasite, leads to a stable host-parasite relationship (host 'tolerance') while antigenic disparity leads to host resistance to the parasite (host 'intolerance')<sup>1-3</sup>. Although the plant does not produce an immune system similar to that in animals, the concept that common antigens between host and parasite might have a role in disease development found some support in plant pathology as well<sup>4,5</sup>. The present investigation is an attempt to see if this concept is applicable in vascular wilt of cotton.

Experiments were designed to look for possible common antigens between two species of cotton, *Gossypium arboreum* L. and *G. hirsutum* L. and a virulent Indian strain of *Fusarium vasinfectum* Atk. Earlier work has shown that this strain is highly pathogenic to *G. arboreum* but not to *G. hirsutum* although it infects and colonizes both to varying degrees<sup>6</sup>. In order to exclude errors owing to non-specific reactions in the final results, the following fungi and plants were included for reference; *Fusarium solani* (Mart.) App. et Wr., *F. culmorum* (W.G. Sm.) Sacc. and *Pyricularia oryzae* Cav. none of which are known parasites of cotton, and *Abelmoschus esculentus* (L.) Moench, and *Phaseolus mungo* L. plants that are not known to be infected by *F. vasinfectum*.

The extraction of the fungal antigens was as described in an earlier paper<sup>7</sup>. For host antigens the initial steps of extraction were the same as outlined by DeVay and co-workers<sup>4</sup>. The material was extracted under liquid nitrogen using polyvinyl pyrrolidone and sodium ascorbate with a pestle and mortar. Further homogenization was done in a VirTis homogeniser. The extractant used was phosphate-buffered saline at pH 7.2. The antigens were purified further by the same procedure as

for fungi<sup>7</sup>. The antigens mixed with Freund's complete adjuvant were administered intramuscularly in a course of six injections to white rabbits (each weighing approximately 1.5 kg). Antisera were collected on 23rd day by bleeding the ear veins and stored at 0° C with merthiolate as preservative. The antisera against the two species of cotton were tested by the agar-gel double diffusion method with their antigens in homologous and heterologous reactions. The antigens of *A. esculentus* and *P. mungo* were also allowed to react with the two antisera. *G. arboreum* formed three lines of precipitation in homologous reactions and two in heterologous reaction with *G. hirsutum* while the latter showed two antigens in homologous as well as heterologous reactions. *A. esculentus*, which belongs to the same family as cotton, shared an antigen with both the species of cotton. *P. mungo* produced no precipitation with either species of cotton.

Using the same technique, the antisera and antigens of the two species of cotton were tested against the antigens and antisera, respectively, of all the test fungi. The antisera of the two species of cotton on reacting with the antigens of *F. vasinfectum*, or the antisera of the latter on reacting with the antigens of the former two, formed a single precipitin band indicating the presence of a common antigen (Fig. 1). However, such a result

FIG. 1. Antigen of *G. arboreum* in the central well (K7) reacting with homologous antiserum (k7) and with heterologous antisera of *G. hirsutum* (mu), *Fusarium vasinfectum* (fv), *F. culmorum* (fc), *F. solani* (fs) and *Pyricularia oryzae* (po).

was not observed in any of the reciprocal reactions involving the other test fungi and the two cotton species, or in those between *F. vasinfectum* and the other plants.

The results of this investigation indicate the presence of a common antigen between the pathogen *F. vasinfectum* and its hosts. However, this

concept of a common antigen between a host and parasite as related to disease development ought, in our opinion, to place emphasis on *parasitism* rather than on *pathogenesis*. The intrinsic ability of the Indian strain of *F. vasinfectum* to infect and colonize (*i.e.*, to parasitize) both the species of cotton, although disease manifestation is seen only in *G. arboreum*, is compatible with this idea. ### EFFECT OF DIFFERENT STORAGE TEMPERATURES ON KEEPING QUALITY OF AVOCADO PEAR FRUITS

It had been known for a long time that low temperature is a good means for keeping fruit after harvest. Low temperature disorders are also a determining factor for storage ability of fruits. Prolonged storage of avocado at 5° C, however, resulted in a declining rate of CO<sub>2</sub> production upon removal to 15° C. Chilling symptoms appeared along with the disturbance of the climacteric pattern (Biale 1941; Pratt and Biale 1944). The lowest temperature at which a rise of respiration was noted in the fuerte avocado was 7.5° C (Biale, 1946).

Mustard (1952) found that different varieties of avocados differ in its sensitivity to chilling injury. Campbell (1960) found that chilling injury occurred in mature pollack avocados stored at 35, 40, 45 and 50° F for 19 to 22 days. Biale and Young (1962) observed that in avocados at 30° F and 35° F, the fruit does not ripen but the tissue darkens.

Aharoni *et al.* (1968) stored avocado fruit at gradually decreasing temperatures, and found that the climacteric peak and softening appeared at the same time in the fruit stored at 12° (prior to the fruit stored at 8° and subsequent to that stored at 14°, 15° and 17° C). The purpose of this work is to study the effect of various storage temperatures on the quality of avocado fruits.

### Materials and Methods

Freshly harvested mature fruits of Duke avocado were sorted out for size, shape, firmness to obtain uniform samples. The fruits were washed with water, then dipped for 5 minutes in solution of 5% borax as a fungicidal treatment and the samples were placed in fiberboard boxes using three carton boxes for each treatment as replicates, then cooled to the required temperatures.

Visual evaluation of the quality was made every 2 days according to the numerical quality score as described by Abdel Kader *et al.* (1968). At the same time unusable fruits were discarded and the causes of decay were recorded. At every sorting time, chilling injury symptoms were observed and noted, and also pathogenes were identified. Experiments were repeated 2 times and the average results are presented.

### Results and Discussion

The relative effects of storage temperatures on quality and decay percentage of "Duke" avocado fruits is illustrated graphically in Fig. 1. Fruits held at room temperature were the first to deteriorate. Their quality loss was mainly a result of senescence as was evidenced by the loss of firmness and the development of black colour. Fruits held at 15° C followed control fruits in their deterioration.

Fig. 1. Effect of temperature on quality and decay percentage of "Duke" avocado fruits during storage.

Avocado fruits that were subjected to 0° C for 5, 10, 15 and 20 days did not show any decay or

deterioration symptoms and also were in good quality during storage at 0° C. However, after removal to room temperature, the rate of decay was so rapid that all fruits were decayed within 2 days. No chilling injury symptoms were noticed on fruits that were stored at 0° C or 5° C before removal to room temperature. After transfer to room temperature the flesh discoloured and some black areas appeared on the skin without developing the texture, characteristic of avocado. In the severe cases the fruits do not ripe at all.

The rate of deterioration at 0° and 5° was of the same order for a period of 20 days. On the other hand, fruits held at 10° C exhibited a faster rate of deterioration although no chilling injury symptoms were observed on them. Fruits stored at 10° C can be kept in a good condition at this temperature for approximately 2 weeks and still have several days for marketing purposes. Fruits held at this temperature deteriorated to an unsalable quality only after 18 days as compared with 6 days for those held at room temperature.

The rate of decay was lower in fruits held at 10° C than those held at room temperature, they reached 50% decay after 17 and 6 days in storage respectively.

Generally, at temperatures much below 10° C. Duke avocado fruits were subjected to the symptoms of chilling injury. Thus, a temperature of 10° C seemed to be the most suitable for storage of Duke avocado fruits.

Avocado fruits were attacked by several pathogens as they became weak as a result of senescence or chilling injury. The identified pathogens included: *Fusarium* sp., *Alternaria* sp., and *Penicillium* sp. in some fruits held at room temperature.

## EMBRYO DEVELOPMENT IN *EUPHORBIA PEPLUS* L.

EMBRYOGENY in the family Euphorbiaceae is of particular interest in view of the reports of widespread occurrence of five major types of embryo development<sup>2-6</sup>. Despite this fact, details of normal embryogeny are available for restricted members. Within the genus *Euphorbia* L., while most of its species, so far embryologically known, display embryogeny conforming to the Euphorbia variation of Onagrad type, *Euphorbia corrigioloides*<sup>7</sup> follows Lotus variation. The report of Scabiosa variation of the Piperad type of embryo development in *Euphorbia rothiana*<sup>8</sup> has since been confuted and shown to conform to the Euphorbia variation of the Onagrad type<sup>3,9</sup>. But in *Euphorbia peltata*<sup>5</sup> and *Euphorbia preslii*<sup>10</sup> the embryo development follows the Chenopodiad and the Piperad type respectively. In view of this variance in embryogeny and since details of description are available for only a few species, the authors deliberate worthwhile studying the embryo development in some more species of *Euphorbia*, and also in the doubtful cases. This communication is concerned with the details of embryo development in *Euphorbia peplus* L.

The zygote (Fig. 2) undergoes a short period of rest and divides when endosperm is 10-nucleate (Fig. 1). Its first division is transverse forming a terminal cell *ca* and basal cell *cb* (Figs. 1, 3). The cell, *ca*, divides vertically (Fig. 4), while *cb* divides transversely to procreate *m* and *ci* (Figs. 5-7) thus producing a 4-celled proembryo (Fig. 6) with cells disposed in three tiers. At times the division of *cb* precedes that of *ca* (Fig. 5) but in our material these cells have never been found to divide synchronously (Figs. 4, 5). The two cells of *ca* divide by another vertical wall in a plane at right angles to the first division (Fig. 7) resulting in a quadrant; the cells of which later divide transversely resulting in octants disposed in two tiers, *l* and *l'* (Figs. 8, 9). The cell, *m*, after longitudinal and transverse divisions becomes the hypophysis (Figs. 8-16). With further differentiation the embryo passes through the globular and heart-shaped stages before it becomes fully differentiated and mature (Figs. 14-18). The cells of the tier *l* give rise to the stem apex (*prt*) and the cotyledons (*pco*), while the derivatives of *l'* function to form the hypocotyledonary region (*phy*) and initials of the central cylinder of the stem (*icc*), *m* to the root cortex (*iec*) and root cap (*co*) and *ci* remains as 1-celled suspensor (*s*).

The course of events taking place in the different tiers of the proembryo is as follows:

In each cell of the terminal tier *l*, an oblique wall is laid down initiating two cells, the inner and

outer (Fig. 10). The former cells on division both transversely and longitudinally over and again differentiate into the plumule, while the latter cells constitute the initials for cotyledons. Concomitantly the cells of the tier *l'* divide periclinally to demarcate the dermatogen (Figs. 11, 12) which likewise develops in the tiers *l* and *m* (Figs. 12–14).

The derivatives of *l'* ultimately contribute to the hypocotyledonary region and the initials of central cylinder of the stem (Figs. 12–16). Subsequent divisions in the inner cells of *l'* demarcate the plerome and perilem (Figs. 14–16).

The basal cell *cb* of the 2-celled proembryo divides by a transverse wall to form *m* and *ci*. The tier *m* which is 1-celled at the 3, 4 and 6-celled stages of the proembryo (Figs. 5–7) functions as a hypophysis initial, divide by a vertical wall forming two juxtaposed cells (Figs. 8–10). The two cells further divide vertically to engender a group of four cells (Fig. 11). Subsequently these divide periclinally to initiate four peripheral cells and four inner cells. The four peripheral cells complete dermatogen of the root tip (Figs. 12–16) as also represent the primordium of the root cap. The inner cells on further division organise two tiers of four cells each (Figs. 13, 14) which constitute the initials of root cortex and finally form the root tip.

The tier *ci* remains as a 1-celled suspensor (Figs. 5–16) which is lost during subsequent development and growth of the embryo in seed (Figs. 17, 18).

The mature embryo is dicotyledonous with well-developed shoot apex, root and vascular supply (Fig. 18).

From the foregoing account it is obvious that the terminal cell, *ca*, of 2-celled proembryo divides by a vertical wall and the basal cell, *cb*, has merely a restricted role in the formation of the embryo proper. Therefore, the embryo development in *Euphorbia peplus* follows the Onagrad type of Johansen<sup>4</sup> and keys out to the Euphorbia variation, as the 6-celled proembryo is disposed in three tiers. Under Souéges scheme (*vide* Crété)<sup>1</sup> it can be matched with the Megarchtype IV, series A in First Period.

The authors thank Prof. T. Sreeramulu (now at Andhra University, Waltair) for kindly interest and facilities and Dr. B. S. M. Dutt for helpful discussions. To Dr. Arne Strid and Mr. E. Baker we are grateful for sending the material. One of us (K. R. R. D.) is thankful to the authorities of Council of Scientific and Industrial Research for awarding Junior Research Fellowship.

### DOUBLE AWNING IN TETRAPLOID RICE

THE present note records the development of awns on both lemma and glume (sterile lemma) in an intervarietal tetraploid grown at Central Rice Research Institute, Cuttack. This variation in awning was expressed in about five percent of the spikelets of the plant. The following observations were recorded in these spikelets: The mid-nerve of the lemma and glume on palea side extended into awns. The awns were either short or medium in length while those developing from the lemma in normal spikelets were always long. The awn bearing glume was broad and 3-nerved enclosing about 3/4 length of the palea. The glume on the lemma side was short and was awnless. The awns developing from the lemma and glume appeared similar. Invariably, one extra glume was also present on the palea side (Fig. 1).

Subsequent studies showed that the variation was teratological in nature. It may be inferred that the nerves of the glumes are also capable of extending into awns. This has been confirmed by Prasad

(Personal communication) who observed a diploid variety where the awn developed from sterile glume. Earlier, the nerves of the lemma and palea were only considered capable of developing into awns<sup>1</sup>.

### VOLATILE SPOROSTATIC FACTORS OF ASPERGILLI AND THEIR ROLE IN SOIL FUNGISTASIS

STUDIES on volatile inhibitors/stimulators have gained momentum in the last few years and several review articles have appeared recently<sup>3-6,7</sup>. Besides their involvement in general growth and development, volatile inhibitors have been implicated in ecology of fungi particularly in soil fungistasis<sup>1,5</sup>. Earlier works in this laboratory have provided valuable data in this direction<sup>8-10</sup>. In continuation of these efforts, production of volatiles by *Aspergilli* was investigated and efforts have been made to correlate these results with soil fungistasis.

Eighteen species of *Aspergillus* used in this study were procured from the Mycology Laboratory, University of Saugar (Table I). Spores of *Alter-*

*naria solani* (Ellis and Martin), *Rhizopus nigricans* Ehrenberg, and *Trichoderma viride* Pers ex. Fries were used as test organisms. Czapek's Dox (CDA) and potato dextrose agar (PDA) media were used for maintaining *Aspergilli* and the test fungi, respectively. Spore suspension of the test fungi was prepared from 4–8 day old cultures, whereas inoculum of the antagonists was 10–15 day old. Routine evaluation of volatile inhibitors was made with a cellophane agar-disc technique<sup>9</sup>; 2% glucose was incorporated in the discs to facilitate germination of test spores. Individual species of *Aspergillus* was either mixed in soil (*in vivo*) or inoculated in CDA (*in vitro*). Sterile cellophane circle was placed over it to avoid contamination of agar discs and a sterile U-tube was kept over it. Agar discs were placed on a sterile glass slide which in turn was supported on the U-tube. The upper lid of the plate was placed back in its original position and the whole assembly was incubated for 10 days. Spore suspension of test fungi was placed on these pre-activated discs and they were further incubated for 8–12 hr. Germination counts for at least 150 spores were made and from this data percentage inhibition was calculated. Sterilized uninoculated soil or CDA was used in the control set of experiments.

In the experiment involving inoculation of sterilized soil by *Aspergilli*, spores of *R. nigricans* were most strongly inhibited (Table I). This was particularly noticeable when antagonists were, *A. fumigatus*, *A. oryzae*, and strains of *A. terreus*; spores of *Alternaria* and *T. viride* were only weakly inhibited: Half of the *Aspergilli* used in this study were ineffective against spores of *Alternaria*. It was visually observed that better fungal growth in soil often resulted in higher inhibition of the test fungus. In contrast to the observations of Singhai<sup>10</sup>, *A. flavus*

III was noted to be a potent inhibitor of all the three test fungi.

Inhibition of test spores was also evident when *Aspergilli* were inoculated individually in CDA. *Aspergillus niger* appeared to be more potent than *A. flavus* III (Table I); inhibition by *A. flavus* I was only slightly weaker. *Aspergillus fumigatus* and *A. terreus* could also bring about considerable inhibition of test spores. Some difference in the performance of antagonists *in vivo* and *in vitro* can be observed. It would appear that a change in the substrate tempers with the growth and thereby results in variable production of volatiles in soil and CDA.

A time-course study of volatile production by *A. flavus* II, *A. niger* and strains of *A. terreus* was undertaken *in vitro* (Table II). *Trichoderma viride* appeared to be most sensitive to the volatiles of these five antagonists since no less than 50% inhibition was noted against them after 8 days of incubation (Table II). Maximum inhibition by *A. flavus* II (71%) against this test fungus was noted after 6 days. *Rhizopus nigricans* ranked second in the order of its sensitivity and exhibited 50–70% inhibition after 8 days of incubation. For these two test fungi some degree of inhibition was evident even after 2 days of growth (Table II); spores of *Alternaria*, however, exhibited none or very little inhibition at this stage.

Further confirmation of the volatile nature of sporostatic factors was obtained by employing two other test procedures, viz., soil emanation agar<sup>5</sup> and paired Petri plates<sup>2</sup>. Inhibition of test spores by *A. flavus* II, *A. niger*, and *A. terreus* I and II was strongly evident in these tests as well (Table III). When the preactivated discs, with strongly inhibited spores, were removed to an ordinary moist chamber the germination percentage increased (Table III,

column II). This suggested an extremely labile nature and fungistatic action of the inhibitory principle(s). Thus soil inhabiting fungi of the genus *Aspergillus* appear to be strong producers of volatile sporostatic factors which have a positive role in ecology of soil fungi especially in the realm of soil fungistasis.

#### BRYOPHYTES AS ROCK BUILDERS—SOME CALCICOLE MOSSES AND LIVERWORTS ASSOCIATED WITH TRAVERTINE FORMATION AT SAHASRADHARA, DEHRA DUN

ALTHOUGH tufa-building bryophytes and other plants have aroused a good deal of interest among ecologists of various countries of Europe and America<sup>1-3</sup>, no such work has so far been carried out in India. Further the need for such studies is emphasized by the ecosensitive character of bryophytes which are the most active agents in

building a biogenic rock like calcareous tufa or travertine. Accordingly the present study of the bryophytes associated with travertine at Sahasradhara was undertaken to fill up this long standing gap in our knowledge. Out of active tufa-building bryophytes, *Barbula gracilentia*, *Bryum cellulare*, *Hymenostyliella involuta*, *Vesicularia montagnei* and *Asterella maculata* are being reported for the first time as tufa-builders. The pottiaceous *Hymenostyliella involuta* previously known only from the Luzon Island in the Philippines (Bartram)<sup>4</sup> has recently been reported from Dehra Dun (Vohra)<sup>5</sup>. The tufaceous nature of this moss is, however, not mentioned in either of the two above-mentioned reports. In the present study, it forms an epiphytic association with the filamentous blue-green alga *Petalonema alatum*, var. *indicum* colonizing the bare boulders of limestone and all tufaceous seeps. Among other associates of tufa formation are calcareous algae like *Chroococcus*, *Gloeothece*, *Merismopedia*, *Petalonema alatum* Berk. var. *indicum* Rao, *Cladophora*, *Nitzschia*, *Pinnularia*, *Tabellaria* and *Cosmarium* and even among these *Merismopedia*, *Petalonema alatum* var. *indicum*, *Pinnularia* and *Tabellaria* are being reported as participants in tufa formation for the first time. Besides, the above forms, a few angiosperms like *Colocasia esculenta* (Linn.) Schott. var. *stolonifera*, *Didymocarpus pedicellata* R.Br., *Epipactis consimilis* Wall., *Eupatorium glandulosum*, H.B. & K., *Itea nultans* Royale and *Primula floribunda* Wall. have also been found to help in building tufaceous rock although they do so only when their exposed parts become covered with an algal or bryophytic felt.

The present study has, to some extent, helped in resolving the controversy about the physico-chemical factors involved in travertine deposition. In particular it shows that biological factors like thick

algal felts and dense moss polsters induce the development of travertine mainly by providing spongy surfaces which can absorb, retain and expose copious thin films of water for effective evaporation and consequent diffusion of  $\text{CO}_2$  from the calcareous spring water thus causing the precipitation of  $\text{CaCO}_3$  in the form of travertine. The mineral matter (calcite) hardens round the mosses taking the mould of their forms and these and other plants act as nuclei around which travertine is deposited.

The vigorous growth rate of these organisms (algae and mosses) seems to exceed the rate of carbonate deposition so that the process of getting cemented below and growing above is continued and the tufa also "grows" up.

These observations generally confirm the views held by Emig<sup>6-7</sup> about the role of plants in the mechanism of travertine deposition at Oklahoma. They also point to the calcicole character of the tufaceous bryophytes, algae and other plants and their indicator value. It would indeed be worthwhile trying some of the angiosperms growing on tufa for cultivation in alkali soils.

#### X-RAY INDUCED ANEUPLOIDY IN *CAPSICUM ANNUM*

THE induction of aneuploidy has been useful in breeding crop plants. Experiments in bread wheat<sup>1</sup> demonstrate the possibility of transferring beneficial chromosomes from comparatively less useful types via aneuploids. Breeding for aneuploids with a view to identifying the chromosomes and linkage groups has also been described in other crops such as barley<sup>2</sup>, tomato<sup>3</sup> and groundnut<sup>4</sup>. The occurrence of aneuploids in members of Solanaceae was reported by Hermesen<sup>5</sup>. The present study concerns

the behaviour of the aneuploid chromosome in meiosis from X2 generation obtained from X-ray irradiated seeds following presoaking.

The seeds of *Capsicum annum* ( $2n = 24$ ) obtained from National Seed Corporation of India, Warangal Branch, were soaked for 6 hours and exposed to radiation at 4000 rads. Meiosis in these plants was studied after fixing the flower buds in acetic acid-alcohol (1:3) and squashing the anthers in aceto-carmine. Mitotical and meiotical aberrations and morphological variations were observed in X1 generation which were continued to X2 generation in order to stabilize the mutants.

In meiotic studies of X2, 90% of their pollen mother cells revealed the presence of an extra chromosome (Fig. 1). Observations on the morphological variations, meiotic aberrations and their subsequent behaviour indicated that all the mutants and their X2 plants carried chromosomal anomalies.

FIG. 1-3. Fig. 1. An extra chromosome at Diakinesis (arrow)  $\times$  ca. 2,000. Fig. 2. The irregular orientation of the extra chromosome at metaphase I (arrow)  $\times$  ca. 2,000. Fig. 3. Anaphase I with lagging and a bridge ( $\times$  2,000).

The most common anomaly was the formation of univalent at diakinesis and the subsequent disturbance resulting from it, such as irregular orientation at metaphase I (Fig. 2) and lagging at anaphase I (Fig. 3).

All the mutants were characterized by the increase in the size of the flower, the height and the yield. Similar characters were observed in 60% of the total number of two hundred plants. While Patil<sup>6</sup> reported adverse effects on *Arachis hypogaea*, economically useful characters such as increase in the yield and early maturity were seen in *Capsicum annum*.

The authors are indebted to the Superintendent, Radium and Cancer Research Institute, Hyderabad, for irradiating the seeds.

#### STOMATAL POLYMORPHISM IN *PRUNUS PADUS* L.

WHILE studying the epidermal structures in Rosaceae, the authors have observed polymorphic stomata in *Prunus padus* L. Since polymorphic stomata have not been reported so far for any member of the Rosaceae, it prompted the publication of this report.

The stomata were studied from the mature leaves obtained from the herbarium specimens of *Prunus padus* collected from Siklis in Nepal. The leaves are hypostomatic with ranunculaceous type of stomata. The stomata were measured at random from different regions of the same leaf and when the measurements (length/breadth) were plotted on a

graph, the stomata fell in three distinct groups (Fig. 1). These three groups of stomata may also

Fig. 1.

be distinguished on the basis of striations pattern. In the largest stomata, the striae extend in all directions with the radiating centres at frequent intervals around the guard cells. The striae arise in two lateral groups in the stomata of medium size. The centre of radiation of striae is not traceable in the smallest stomata and they pass parallel to the guard cells. The average number of stomata per sq. mm is 604 taken all the three types together. Out of these 53.1% are the smallest; 30.4% of the middle size and 16.5% of the largest size. The means and standard deviations of the three sizes of stomata is given in Table I.

TABLE I

|         | Size of stomata in μ |           |           |
|---------|----------------------|-----------|-----------|
|         | Small                | Medium    | Large     |
| Length  | 8.5 ± .6             | 11.4 ± .5 | 15.1 ± .7 |
| Breadth | 6.4 ± .6             | 8.6 ± .9  | 10.5 ± .3 |

#### OXYGEN CONSUMPTION AND METABOLIC RATE IN RELATION TO BODY SIZE IN *MARTESIA STRIATA* (LINN.)

STUDIES on the oxygen consumption of marine wood boring organisms are very few<sup>1,4</sup>. Eltringham<sup>4</sup> recorded consumption of oxygen in relation to salinity in a crustacean wood borer *Limnoria*. Lane and Co-workers<sup>1,2</sup> examined the oxygen consumption of both adult and larval forms of molluscan wood borer *Teredo*. In India, respiratory studies on the pholad wood borer *Martesia fragilis* in relation to body size have been undertaken from Madras harbour<sup>3</sup>. Water filtration rate of another pholad *M. striata*, of Visakhapatnam, has been studied by Nagabhushanam<sup>5</sup>, but the relationship between body size and oxygen consumption of this local species is not known. In the present investigation, work was therefore initiated to examine the respiration of *M. striata* (Linn.) and to determine the metabolic rate in relation to body size.

Animals of different sizes were removed from the timber exposed at Visakhapatnam harbour without damaging their shell and the experiments were conducted at temperature  $25^{\circ} \pm 0.5^{\circ} \text{C}^{\circ}$ . Animals (0.077 g to 1.02 g) were taken in individual respiratory chambers and the total oxygen consumed was determined at the end of four hours.

The relationship between the body size and oxygen uptake has been obtained from the following equation<sup>7</sup>:

$$Y = a.X^b$$

where  $Y$  = oxygen consumption in ml/hr,  $X$  = the body weight, while  $a$  &  $b$  are constants.

The value of  $b$  in the above equation was determined to be 0.5665 and is thus nearer to the two-thirds power of body weight. A regression curve of oxygen consumption to body size (Fig. 1)

FIG. 1. Double log plot of oxygen consumption vs body weight in *Martesia striata*.

FIG. 2. Double log plot of metabolic rate against body weight.

shows that the oxygen consumption of animal increases with an increase in the size. The oxygen

consumption varied from 0.131 to 0.7880 ml/hr in the various size groups examined. The oxygen consumption per unit weight or metabolic rate varied from 0.2664 to 2.202 ml/gm/hr being inversely proportional to the body size (Fig. 2).

Although oxygen consumption in *M. striata* shows an exponential relationship to body size, in the same size group itself great variations were evident (Fig. 1). Ghiretti<sup>8</sup> observed that metabolic rate varied widely within a single species as a result of both intrinsic and extrinsic factors in molluscs. Further even under constant external conditions, the oxygen consumption of a given specimen is extremely variable<sup>8</sup>. The variations recorded in the experiments therefore do not show tendencies unusual to bivalves. The value of  $b$  observed in the present studies was also found to be very close to the value obtained for an allied wood borer *M. fragilis* earlier<sup>3</sup>.

The authors are grateful to Captain P. R. Sen, IN., Director, and Sri. S. V. S. Rao, Deputy Director of this laboratory, for their encouragement to this investigation.

#### CROSSING TECHNIQUE IN MUNG BEAN (*PHASEOLUS AUREUS* ROXB.)

ARTIFICIAL crossing in *Phaseolus* species is considered to be a difficult proposition, primarily due to high percentage of flower drop. Coupled with this problem is the lack of precise information about the technique of crossing. Boiling *et al* (1961) have described the method of emasculation and pollination but have not given any information about the appropriate time of emasculation and pollination. A preliminary investigation was, therefore, undertaken to determine the optimum time

TABLE I

of emasculation, pollination and the selection of proper bud stage.

This investigation was confined to early, semi-early and developed stages of immature mung. ME1 and ME4 (ME1 was used as female parent and ME4 as male parent). Two different times of emasculation and pollination, i.e. morning from 8.00 to 11.00 a.m. and evening from 4.00 to 6.30 p.m. were chosen. The results in four combinations, namely (i) morning emasculation, morning pollination; (ii) morning emasculation, evening pollination; (iii) evening emasculation, evening pollination and (iv) evening emasculation followed by pollination next morning. Buds of three different stages recognized by the colour, i.e. green, yellowish green, and greenish yellow, were emasculated. The emasculation and pollination of flower buds were done as suggested by Hoeling *et al.* (1961). At the time of pollination the emasculated buds were observed to be closed, opened and dropped. It was noted that emasculated buds of green colour either dropped before pollination or during pollination. Yellowish green emasculated buds were fully blossomed (open stage) while greenish yellow emasculated buds were observed to be closed at the time of pollination. Therefore, only the last two categories of buds were pollinated.

The emasculated buds were pollinated according to the schedule. The data regarding the flowers emasculated and the pod setting in different flower stages are presented in Table I.

It is clear from Table I that evening emasculation followed by next morning pollination gave the highest pod setting of 17 pods out of 102 buds emasculated (17%). and the next in order was the morning emasculation followed by evening pollination resulting in 11 pods out of 86 buds emasculated (13%). Based on number of pollinations made the per cent pod setting was 20% and 14% respectively. Furthermore, it was noted that simultaneous emasculation and pollination either in the morning or evening gave very low pod set, viz. 5.6%.

It was very much interesting to note that the flowers that remained closed at pollination time did not set any pod while whole of the pod setting was obtained in those buds which blossomed (buds) opened at the pollination time. Non setting of pods in the flowers that were closed at pollination time may be due to the fact that the female was not more receptive.

It is therefore suggested from the present study that high percentage of pod setting in *Phaseolus mungo* can be obtained by following emasculation of yellowish green (opened) stage buds in the evening (4.00 p.m. to 6.30 p.m.) and pollination of only blossomed flowers in the next morning (8.00 a.m. to 11.00 a.m.). The applicability of these findings was also tested in interspecific hybridization between *Phaseolus mungo* and *Phaseolus mungo* and a pod setting up to 34% has been achieved.

## ONTOGENY, STRUCTURE AND DISTRIBUTION OF TRICHOMES ON THE FLORAL PARTS OF *CITRUS COROMANDELICA* VAHL.

Various types of trichome occur on plants and their taxonomic significance has been emphasized by several workers, especially in respect of the Umbelliferae (Compositae) (Carlquist<sup>1,2</sup>, Ramayya<sup>3</sup>), Labiales (Heintzelman and Howard<sup>4</sup>), Labiate (Mathias<sup>5</sup>), Gentianaceae (Laroche and Siddiqui<sup>6</sup>) and Scrophulariaceae (Kaur<sup>7</sup>). Bachmann<sup>8</sup> investigated the structure of hairs in many angiosperm taxa and presented a key for their identification.

The present note deals with the ontogeny, structure and distribution of trichomes on the floral parts of *Citrus coromandeliana*. The buds and flowers were collected from the bank of river

Animals of different sizes were removed from the timber exposed at Visakhapatnam harbour without damaging their shell and the experiments were conducted at temperature  $25^{\circ} \pm 0.5^{\circ} \text{C}^{\circ}$ . Animals (0.077 g to 1.02 g) were taken in individual respiratory chambers and the total oxygen consumed was determined at the end of four hours.

The relationship between the body size and oxygen uptake has been obtained from the following equation<sup>7</sup>:

$$Y = a \cdot X^b$$

where  $Y$  = oxygen consumption in ml/hr.  $X$  = the body weight, while  $a$  &  $b$  are constants.

The value of  $b$  in the above equation was determined to be 0.5665 and is thus nearer to the two-thirds power of body weight. A regression curve of oxygen consumption to body size (Fig. 1)

FIG. 1. Double log plot of oxygen consumption vs body weight in *Martesia striata*.

FIG. 2. Double log plot of metabolic rate against body weight.

shows that the oxygen consumption of animal increases with an increase in the size. The oxygen

consumption varied from 0.131 to 0.7880 ml/hr in the various size groups examined. The oxygen consumption per unit weight or metabolic rate varied from 0.2664 to 2.202 ml/gm/hr being inversely proportional to the body size (Fig. 2).

Although oxygen consumption in *M. striata* shows an exponential relationship to body size, in the same size group itself great variations were evident (Fig. 1). Ghirelli<sup>8</sup> observed that metabolic rate varied widely within a single species as a result of both intrinsic and extrinsic factors in molluscs. Further even under constant external conditions, the oxygen consumption of a given specimen is extremely variable<sup>8</sup>. The variations recorded in the experiments therefore do not show tendencies unusual to bivalves. The value of  $b$  observed in the present studies was also found to be very close to the value obtained for an allied wood borer *M. fragilis* earlier<sup>8</sup>.

The authors are grateful to Captain P. R. Sen, IN., Director, and Sri. S. V. S. Rao, Deputy Director of this laboratory, for their encouragement to this investigation.

#### CROSSING TECHNIQUE IN MUNG BEAN (*PHASEOLUS AUREUS* ROXB.)

ARTIFICIAL crossing in *Phaseolus* species is considered to be a difficult proposition, primarily due to high percentage of flower drop. Coupled with this problem is the lack of precise information about the technique of crossing. Boiling *et al* (1961) have described the method of emasculation and pollination but have not given any information about the appropriate time of emasculation and pollination. A preliminary investigation was, therefore, undertaken to determine the optimum time

of emasculatation, pollination and the selection of proper bud stage.

This investigation was conducted using two newly developed strains of mungbean, namely, ML1 and ML4. ML1 was used as female parent and ML4 as male parent. Two different times of emasculatation and pollination, viz., morning from 8-00 to 11-00 a.m. and evening from 4-00 to 6-30 p.m. : were chosen. This resulted in four combinations, namely : (i) morning emasculatation, morning pollination, (ii) morning emasculatation, evening pollination, (iii) evening emasculatation, evening pollination and (iv) evening emasculatation followed by pollination next morning. Buds of three different stages recognised by the colour, viz., green, yellowish green, and greenish yellow were emasculated. The emasculatation and pollination of flower buds were done as suggested by Boiling *et al.* (1961). At the time of pollination the emasculated buds were observed to be closed, opened and dropped. It was noted that emasculated buds of green colour either dropped before pollination or during pollination. Yellowish green emasculated buds were fully blossomed (open stage), while greenish yellow emasculated buds were observed to be closed at the time of pollination. Therefore, only the last two categories of buds were pollinated.

The emasculated buds were pollinated according to the schedule. The data regarding the flowers emasculated and the pod setting in different flower stages are presented in Table I.

It is clear from Table I that evening emasculatation followed by next morning pollination gave the highest pod setting of 17 pods out of 102 buds emasculated (17%) and the next in order was the morning emasculatation followed by evening pollination resulting in 11 pods out of 86 buds emasculated (13%). Based on number of pollinations made the per cent pod setting was 20% and 14% respectively. Furthermore, it was noted that simultaneous emasculatation and pollination either in the morning or evening gave very low pod set, viz., 5-6%.

It was very much interesting to note that the flowers that remained closed at pollination time did not set any pod, while whole of the pod setting was observed in those buds which blossomed (remained open) at the pollination time. Non-setting of pods in the flowers that were closed at pollination time may be due to the fact that the female was no more receptive.

It is, therefore, suggested from the present study that high percentage of pod setting in *Phaseolus aureus* can be obtained by following emasculatation of yellowish green (open) stage) buds in the evening (4.00 p.m. to 6.30 p.m.) and pollination of only blossomed flowers in the next morning (8-00 a.m. to 11.00 a.m.). The applicability of these findings were also tested in interspecific hybridization between *Phaseolus aureus* and *Phaseolus mungo* and a pod setting up to 34% has been achieved.

# ONTOGENY, STRUCTURE AND DISTRIBUTION OF TRICHOMES ON THE FLORAL PARTS OF *CELSIA COROMANDELIANA* VAHL.

VARIOUS types of trichome occur on plants and their taxonomic significance has been emphasized by several workers especially in respect of the families Compositae (Carlquist<sup>2-4</sup>, Ramayya<sup>9</sup>); Icacinaceae (Heintzelman and Howard<sup>6</sup>); Labiatae (Mathur<sup>8</sup>); Lentibulariaceae (Farooq and Siddiqui<sup>5</sup>) and Scrophulariaceae (Kaur<sup>7</sup>). Bachmann<sup>1</sup> investigated the structure of hairs in many angiosperm taxa and presented a key for their identification.

The present note deals with the ontogeny, structure and distribution of trichomes on the floral parts of *Celsia coromandeliana*. The buds and flowers were collected from the bank of river

Yamuna, Delhi, and were fixed in formalin-acetic-alcohol. Conventional methods of dehydration, infiltration and embedding were followed. Sections were cut at a thickness of 5–8 microns and stained either in safranin or iron-alum haematoxylin with fast green as counterstain.

**Trichomes on Bracts and Sepals.**—The trichome is initiated as a protuberance from any epidermal cell which is distinguishable by its dense cytoplasm and conspicuous nucleus (Fig. 1A). This cell elongates and divides transversely to form a terminal and a basal cell (Fig. 1B). Further divisions are confined to the terminal cell whereas the basal cell

functions as the foot (Fig. 1B–F). The derivatives of the terminal cell lead to the formation of a file of two (Fig. 1C), three (Fig. 1D) and four cells (Fig. 1E). Further divisions in the apical cell of the file, however, are vertical and result in the formation of head (Fig. 1F–H). In its final structure the multicellular trichome can be divided into three regions: (a) Foot, (b) Stalk, made up of 3 or 4 septate, highly vacuolated cells, with meagre cytoplasm and (c) Head, comprising 4 to 8 cells with dense cytoplasm and prominent nuclei. Trichomes of this type occur abundantly on bracts and sepals, are absent from the petals and sporadically occur on the pistil.

**Trichomes on Stamens.**—The trichomes on the basal part of the filament are long, unicellular and non-septate. An epidermal cell destined to develop as a trichome elongates to form a long, unicellular structure (Fig. 1I–M). The nucleus, which is initially situated at the base (Fig. 1J), migrates towards the tip as the hair matures (Fig. 1M).

Studies on the ontogeny, structure and distribution of the epidermal appendages of the floral parts of *Verbascum thapsus* (unpublished observations) show that they are characterised by the presence of highly branched trichomes on the bracts and sepals. The pistil is also heavily clothed with numerous branched hairs. *Celsia coromandeliana* differs from *Verbascum thapsus* in having uniseriate trichomes on bracts and sepals and very few trichomes on the pistil. The present study indicates that *C. coromandeliana* is not *pro parte V. thapsus* and supports their status as independent taxa.

It gives me great pleasure to express my gratitude to Dr. M. R. Vijayaraghavan for encouragement and suggestions.

## SHORT SCIENTIFIC NOTES

### Phytochemical Studies on *Cassia* Species of Indian Arid Zone

Sennosides are the active principles of senna and are well known for their medicinal importance<sup>3,4</sup>. Although sennoside percentage of Tinnevely senna (*C. angustifolia*) and Alexandrian senna (*C. acutifolia*) has been estimated earlier, so far no such work has been done on *Cassia* species growing in Indian arid zone<sup>1,2</sup>. During the present investigation an attempt has been made to estimate the

in the leaves and seeds of wild *C. angustifolia* have been reported to be 3.0 to 5.0 and 2.4 to 3.0% respectively<sup>6,7</sup>.

Grateful thanks of the authors are due to ICAR, New Delhi, for the scheme sanctioned to one of us (DDC), which made this study possible. They are also thankful to Professors H. C. Arya and R. C. Kapoor for the facilities provided and to Dr. D. N. Sen, Reader in Botany, for guidance and critically reading the manuscript.

TABLE I  
Percentage of sennoside contents in the leaf samples of *Cassia* species

sennoside contents in the leaves of various *Cassia* species from Western Rajasthan.

For this study, the leaves samples were first air dried at room temperature. All the measurements were recorded on Spectronic-20 spectrophotometer, and sennoside estimation was done as reported in B.P.C. (British Pharmacopoeia)<sup>2,5</sup>. Besides the total sennosides content in *Cassia* leaves the rhein carboxylic derivatives, equivalent to sennoside B, have also been estimated. The experimental observations for plant materials (leaves) and their sennoside contents has been presented in Table I.

It appeared from the present studies that *C. angustifolia* contained highest sennoside contents followed by *C. fistula*. It was interesting to note that besides sennosides, the percentage of rhein was also maximum in *C. angustifolia* when compared with other *Cassia* species. The sennoside contents

**Fruit Rot of *Trichosanthes dioica* L. Caused by *Pythium cucurbitacearum* Takimoto in West Bengal**

Plants belonging to the family Cucurbitaceae are susceptible to a few *Pythium* spp. Commonest infections are those caused by *P. aphanidermatum* (Ed.) Fitz<sup>1</sup>. Takimoto (1941) from Japan first reported *P. cucurbitacearum* sp. nov. on a few cucurbitaceous plants. Samples of rotten fruits of *Trichosanthes dioica* collected from fields of Nadia District, West Bengal, has yielded *P. cucurbitacearum* Tak.

Infections generally start from the styler end and characteristically cause extensive soft rotting with fine mycelial growth on the surface at later stages. Diagnostic characters of the species as noted on host are as follows:

Hyphae broad, 4–6  $\mu$  in breadth; zoosporangia papillate, terminal, on short sporangiophores, mostly spherical, varying to ovoid, thin-walled with granular protoplast, measuring 22–35  $\mu \times$  20–30  $\mu$ ; oogonia, on long slender hyphae, are spherical containing mostly central, rarely peripheral oosphere, measuring respectively, 20–25  $\mu$  and 12–16  $\mu$  in diameter. Antheridia (lobes) nearly spherical to clavate, making basal contact with oogonial lobe at the point of its origin, may be rarely bilobed, measuring 8–10  $\mu$  in diameter. Copulation amphigynous, antheridial nucleus passing apparently through a pore at contact. Oospores spherical, thick-walled, uniform, measuring 15–18  $\mu$ .

The species *P. cucurbitacearum* Tak. is a new record for India and *Trichosanthes dioica* is an addition to the list of its hosts. Material is preserved in the Herbarium, Department of Plant Pathology, Kalyani University.

**Morphogenesis in Seed Cultures of *Spathoglottis***

Orchids produce millions of seeds per capsule, but only a few germinate and attain blooming. The orchid breeders generally follow vegetative propagation. For over 50 years successful attempts have been made to germinate orchid seeds on agar media<sup>1,2</sup>. This communication describes the germination of seeds, and morphogenesis of embryo in *Spathoglottis plicata* in vitro.

For the present investigation, the plants with violet flowers were selected. The seeds were asepti-

cally scooped from mature capsules, and were placed on a modified White's agar medium with 2% sucrose (BM), and also on BM supplemented with casein hydrolysate (CH), coconut milk (CM), 2, 4-D, IAA, NAA, and kinetin, individually and in different combinations. Each culture received about 40 seeds, and cultures were maintained under controlled conditions of light (8–10 ft candles), temperature (25°C  $\pm$  2) and humidity (about 60%).

The seeds at culture contained an undifferentiated embryo enclosed by a thin, transparent seed coat. In the majority of the cultures, they swelled within 2–3 weeks. On BM about 45% seeds germinated. On the contrary, a significant response was noted on BM + CM (10%) and BM + CH (1000 ppm) with 60% and 80% germination, respectively, and satisfactory growth of seedlings. But, on BM + CM (10%) + CH (1000 ppm) + IAA (1 ppm) + kinetin (1 ppm) and BM + CH (1000 ppm) + IAA (1 ppm) + 2, 4-D (ppm) only 25% and 20%, respectively, produced seedlings. During germination, the swollen embryo emerged from the seed coat as a creamy-white, or greenish, spherule which later developed into a 'top'-shaped protocorm with numerous unicellular rhizoids. Within 6–7 weeks of culture, from the protocorm differentiated a shoot apex which developed into a shoot with 2 or 4 leaves; and 2 or 3 roots in another 2 weeks. By about the 13th week we obtained a fully-differentiated plant with 6–8 leaves and 4–6 roots.

In addition, the seeds also exhibited several interesting features like callusing, abnormal seedlings with thick, negatively-geotropic roots, and differentiation of adventitious buds on protocorms. The buds further developed into multiple shoots. The callus was subculturable, and rapid growth occurred on BM + 2,4-D (0.5 and 1 ppm) + NAA (0.5 to 2 ppm). When subcultured on BM, 8% cultures differentiated roots, whereas on BM + CH (1000 ppm) 90% cultures developed vigorously growing roots.

The hypocotyl segments showed a high degree for differentiation of roots and shoots resulting in plantlets. The latter were transferred to pots containing vermiculite and, subsequently, soil. In the green house the plantlets developed several new leaves and reached a height of 15–20 cm in about 4 weeks.

# Occurrence of Giant Potholes in the Deccan Trap Lava Flows

Formation of potholes though quite characteristic of the sedimentary rock formations, particularly those of the limestone formations in many parts of the country, they are not so common in the Deccan Trap lava flows. The Kukari river, a tributary to Ghod river in Bhima basin, has given rise to some excellent potholes near village Nighoj (Toposheet No. 47 J/5. Quadrant 1 A, 18° 56' : 74° 16' R.L. 588 metres above m.s.l.). The river has a perennial flow at this place but the stream has water falls (45 m deep) at the location of the potholes. The potholes exist only locally for about half a kilometer in the direction of the stream, with cascade flow due to ungraded slope of the stream bed. The diameter of the giant potholes vary from 1 meter to 3 meters, the depth being about 80 meters. In the advanced stages, the potholes are interconnected along the side walls.

The bedrock of the lava flow is quite hard and compact nevertheless the stream has chiselled out the huge bowels. The following sequence of the lava flows could be demarcated :

I. Top-flow : Greyish, hard and compact, well jointed, highly siliceous, porphyritic basalt. Nodules of cryptocrystalline silica are abundant. Thin veins of brecciated basalt about 10 cm in width criss-cross this flow.

II. Second-flow : Greyish black, poorly jointed hard and compact fine grained basalt.

The agate-rich surface lava flow with pentagonal joints shows circular rings of iron bands inside the pentagons suggesting the potential nuclei of future potholes.

# LIQUID CRYSTALS

Proceedings of the International Conference held at the  
Raman Research Institute, Bangalore, 3-8 December 1973

*Edited by* S CHANDRASEKHAR  
Raman Research Institute  
Bangalore 560006, India

April 1975, *ca* 450 pages, \$27.00

This book forms the full proceedings of the International Conference on Liquid Crystals held in December 1973, to mark the 25th anniversary of the founding of the Raman Research Institute, Bangalore. It presents original research papers and state-of-the-art reports by many leading liquid crystal scientists on a wide range of topics of current interest from the physics and chemistry of liquid crystals to their device applications.

This authoritative volume will interest solid state theorists, surface chemists, synthetic organic chemists and graduate students.

# X-RAY INTENSITY STATISTICS OF APPROXIMATELY CENTROSYMMETRIC STRUCTURES\*

R. SRINIVASAN AND P. SWAMINATHAN

Centre of Advanced Study in Physics, University of Madras, Guindy Campus, Madras-600025, India

## ABSTRACT

The joint probability distribution of X-ray structure factors of a non-centrosymmetric structure (true structure) and that of a centrosymmetric structure (assumed model) from which it deviates slightly, are given. These are characterised by a parameter  $D = \langle \cos 2\pi \mathbf{H} \cdot \Delta \mathbf{r}_j \rangle$  where  $\Delta \mathbf{r}_j$  are the deviations of the  $N$  atoms from the centrosymmetric arrangement. The limiting forms of the distribution for  $D = 0$ , and  $D = 1$  are respectively the acentric and centric distributions of Wilson. Intermediate values of  $D$  characterise different degrees of centrosymmetry of the structure. The parallelism of the results to another 'approximately centrosymmetric' situation (Srinivasan, *Indian J. Pure Appl. Phys.*, 1965, 3, 187), is pointed out.

## 1. INTRODUCTION

IN a series of papers from this laboratory (Ramachandran *et al.*, 1963; Srinivasan *et al.*, 1963 *a, b*; 1964; Srinivasan and Ramachandran, 1965 *a, b*; 1966; Srinivasan and Chandrasekharan, 1966; Parthasarathy and Srinivasan, 1967) the statistical distribution of a pair of structure factors have been considered. The results obtained therein have been shown to be applicable to different stages of crystal structure refinement as well as for testing of isomorphism between a pair of crystals. The probability distributions established were for a pair of structure factors,  $F_N$  and  $F_P^c$  where  $F_N$  corresponds to the true structure containing  $N$  atoms and  $F_P^c$  to the assumed model containing a part ( $P$  atoms) of the structure whose coordinates  $\mathbf{r}_{Pj}^c$  differ from the true  $\mathbf{r}_{Nj}^c$  by  $\Delta \mathbf{r}_{Nj}$ . Broadly, two cases have been considered so far namely (a) when both  $F_N$  and  $F_P^c$  are non-centrosymmetric (case I) and (b) when both  $F_N$  and  $F_P^c$  are centrosymmetric (case II). The various results that have been deduced are thus applicable to a crystal structure which is known to be either non-centrosymmetric or centrosymmetric as the case may be.

The possibility that  $F_P^c$  could correspond to a centrosymmetric model while  $F_N$  is non-centrosymmetric (we shall refer to this as case III) and *vice versa* (case IV) was not considered earlier since it was thought that this might not have immediate practical application. It has however been realised now that these cases are also of interest since they could lead to distributions for pseudosymmetric structures.† Consider for simplicity the case  $P = N$ .

It is possible to imagine a structure which is in reality non-centrosymmetric while the assumed model is centrosymmetric. Following the basic problem posed for cases I and II, we postulate that the  $N$  atoms of the true structure are related to the  $N$  atoms of the assumed model through the given set of errors  $\Delta \mathbf{r}_{Nj}$ . Since the assumed model is centrosymmetric for the present case, this would mean that the true model could better be described as "approximately centrosymmetric". Thus one would expect that as  $\Delta \mathbf{r}_{Nj}$  tend to zero the distribution would tend to be a centric one while when  $\Delta \mathbf{r}_{Nj}$  tend to be large the distribution would tend to the acentric one. For intermediate values of  $\Delta \mathbf{r}_{Nj}$  the distribution can be taken to represent different degrees of centrosymmetry of a non-centrosymmetric structure.

It would appear that the statistics of such a situation was first considered by Luzzati (1953) who applied his earlier analysis (1952) to the above problem and worked out theoretically the values to be expected for a type of discrepancy index involving  $F_N$  and  $F_N^c$  which would enable one to use the results to deduce  $\langle |\Delta \mathbf{r}_{Nj}| \rangle$  for a practical case. His treatment of the problem is brief and is restricted to the statement of a few results. Recently this aspect of the problem has been considered in this laboratory in detail following the type of analysis done for cases I and II. The purpose of this paper is to outline briefly some of the main steps involved in deducing the distributions and the possible application of these to develop other statistical criteria. Most of these could be deduced following the same procedures as for cases I and II and in conjunction with Luzzati's treatment (1953).

It may be mentioned that the problem of this type of degree of centrosymmetry of a non-centrosymmetric structure was also recently considered in this laboratory (Srinivasan and Vijayalakshmi, 1972 *a, b*; Srinivasan *et al.*, 1974; Srinivasan, Swaminathan and Chacko, 1972) and the present

\* Contribution No. 393 from the Centre of Advanced Study in Physics, University of Madras, Madras-600025, India.

† Following Srinivasan (1965 *a*) we use this term pseudosymmetry in a very general sense to denote the presence of any non-crystallographic symmetry property associated with the "asymmetric part" or "crystallographic unit" so as to invalidate the basic Wilson conditions.

analysis forms, in part, an extension of the above studies.

## 2. BASIC PROBABILITY DISTRIBUTIONS

Let  $r_{Nj}$  denote the true coordinates of the structure which is approximately centrosymmetric. These may be considered to have been obtained by giving random and independent displacements  $\Delta r_{Nj}$  to the coordinates of a perfectly centrosymmetric assumed model. It is assumed that the shifts  $\Delta r_{Nj}$  and  $\Delta r_{Nj'}$  for the atoms  $j$  and  $j'$  which are related by centrosymmetry are random and independent where  $n = N/2$ . We denote by  $F_N$  and  $F_N^c$  the structure factors of the true and assumed structures. It is also assumed that both the true and assumed structures satisfy the ideal Wilson conditions, namely, they contain large number of similar atoms randomly distributed in the unit cell.

The establishment of conditional distribution  $P(F_N; F_N^c)$  follows closely the steps given earlier (e.g., see Appendix 1 of Srinivasan and Chandrasekharan, 1966) and is not detailed here.† The conditional distribution  $P(F_N, F_N^c)$  takes the form

$$P(F_N; F_N^c) = \frac{1}{\pi \sigma_N^2 (1 - D^2)} \exp \left[ - \frac{F_N^2 - D^2 (F_N^c)^2 - 2D F_N F_N^c \cos \alpha}{\sigma_N^2 (1 - D^2)} \right] \quad (1)$$

where  $D = (\cos 2\pi H \cdot r_{Nj})$ ,  $\sigma_N^2 = \sum_{j=1}^N f_j^2$

and  $\alpha$  is the angle between  $F_N$  and  $F_N^c$ . The joint distribution  $P(F_N, \alpha; F_N^c)$  for a given  $F_N^c$  is

$$P(F_N, \alpha; F_N^c) = \frac{|F_N|}{\pi \sigma_N^2 (1 - D^2)} \exp \left[ - \frac{F_N^2 - D^2 (F_N^c)^2 - 2D F_N F_N^c \cos \alpha}{\sigma_N^2 (1 - D^2)} \right] \quad (2)$$

where  $\alpha = \alpha_N - \alpha_N^c$ . In terms of normalised variables  $y_N = F_N / \sigma_N$ ,  $y_N^c = F_N^c / \sigma_N$  we have

$$P(y_N, \alpha; y_N^c) = \frac{y_N}{(1 - D^2)} \exp \left[ - \frac{y_N^2 - D^2 (y_N^c)^2 - 2D y_N y_N^c \cos \alpha}{(1 - D^2)} \right] \quad (3)$$

$$P(y_N; y_N^c) = \frac{2y_N}{(1 - D^2)} \exp \left[ - \frac{y_N^2 - D^2 (y_N^c)^2}{1 - D^2} \right] I_0 \left[ \frac{2D y_N y_N^c}{1 - D^2} \right] \quad (4)$$

† The number of atoms in the model and true structure are denoted here by  $N$  while in the paper cited (Srinivasan and Chandrasekharan, 1966) it was denoted by  $P$ . Also the only other difference is that  $F_N^c$  now corresponds to a centrosymmetric model.

It is important to note that while  $F_N$  has both amplitude and phase,  $F_N^c$  is real since it corresponds to a centrosymmetric model. Thus assuming a centric distribution for  $P(y_N^c)$

$$P(y_N^c) = \sqrt{2\pi} \exp \left[ - (y_N^c)^2 / 2 \right] \quad (5)$$

the joint distribution  $P(y_N, y_N^c)$  is readily deduced to be

$$P(y_N, y_N^c) = \sqrt{2\pi} \frac{2y_N}{(1 - D^2)} \exp \left[ - \frac{2y_N^2 - (1 - D^2)(y_N^c)^2}{2(1 - D^2)} \right] I_0 \left[ \frac{2D y_N y_N^c}{(1 - D^2)} \right] \quad (6)$$

The distribution of  $\alpha$  for a given  $F_N$ ,  $F_N^c$  will be useful. This is given by

$$P(\alpha; F_N, F_N^c) = \frac{1}{2\pi} \frac{\exp \left[ - \frac{2D F_N F_N^c \cos \alpha}{\sigma_N^2 (1 - D^2)} \right]}{I_0 \left[ \frac{2D F_N F_N^c}{\sigma_N^2 (1 - D^2)} \right]} \quad (7)$$

So also, the actual distribution of phases,  $\alpha$  can be deduced from (3) by substituting for  $P(y_N^c)$  corresponding to centric distribution and integrating over  $y_N$  and  $y_N^c$ . The expression is not given here.

## 3. DISCUSSION OF THE RESULTS

The above results form the basis for working out a number of statistical results of interest. For instance the availability of the joint distributions  $P(y_N, y_N^c)$  enables us to study distributions of variables such as the difference  $y_d = (y_N - y_N^c)$  (and also product, quotient, etc.). These will be considered in detail in a later paper. However, we shall deduce here one interesting result concerning the distribution  $P(y_N)$  alone. Thus integration over  $y_N^c$  in (6) leads to the marginal distribution  $P(y_N)$  to be

$$P(y_N) = \frac{2y_N}{\sqrt{1 - D^2}} \exp \left[ - (y_N^2 / (1 - D^2)) \right] I_0 \left[ \frac{D^2 y_N^2}{1 - D^2} \right] \quad (8)$$

This may be compared with the probability distribution of the normalised amplitude for another situation of "an approximately centrosymmetric structure" considered earlier in the literature (Srinivasan, 1965 *a, b*). This deals with the case of a non-centrosymmetric structure (space group  $P1$ ) containing a centrosymmetric and a non-centrosymmetric group. The distribution for such a case turns out to be‡

$$P(y_N) = \frac{2y_N}{\sqrt{1 - \sigma_1^4}} \exp \left[ - (y_N^2 / (1 - \sigma_1^4)) \right] I_0 \left[ \frac{\sigma_1^2 y_N^2}{1 - \sigma_1^4} \right] \quad (9)$$

‡ Although Srinivasan (1965 *a*) gave for this case  $P(y_N)$  as an integral his expression can be reduced using standard integral tables (Gradshteyn *et al.*, 1965) to the above form.

where  $\sigma_1^2$  stands for the ratio of the mean square amplitudes corresponding to the centric group to that of the entire structure. A comparison of (8) with (9) shows that the final distributions are identical in form except for the appearance of  $D$  in (8) in place of  $\sigma_1$  in (9). The parallel roles of  $\sigma_1$  and  $D$  are now obvious. Thus the two limits  $D=0$  (or  $\sigma_1=0$ ) and  $D=1$  (or  $\sigma_1=1$ ) correspond to acentric and centric distributions. Intermediate values of  $D$  (or  $\sigma_1$ ) correspond to different degrees of centrosymmetry. Thus  $D$  (or  $\sigma_1$ ) may be taken as a quantitative measure of the degree of centrosymmetry of the structure. In fact it may be pointed out that Srinivasan *et al.* (1972) suggested earlier the use of  $D$  for this purpose and the present results only supply a sound theoretical justification for the same. The curves of  $P(y_N)$  given as a function of  $\sigma_1^2$  in the earlier paper (Srinivasan, 1965 *a, b*) are applicable here.

It may be mentioned that  $D$  can be estimated in practice by working out some of the statistical parameters connected with  $y_N$ . For instance, the moments or variance of  $y_N$  can be worked out which turn out to be functions of  $D$ . However, these may not be very sensitive especially when  $\Delta r_{Nj}$  are small. It seems preferable to turn to other statistical parameters involving quantities  $y_N$  and  $y_N^c$  such as say the difference  $y_d = y_N - y_N^c$ . Since it measures the deviation of  $y_N$  from that of the assumed model, this and other related parameters such as reliability indices based on it may be expected to be more sensitive.

We may also mention here that since  $y_N$  and  $y_N^c$  now involve non-centrosymmetric and centrosymmetric combination, distributions connected with pair such as say the quotients  $y_N/y_N^c$ ,  $y_N^c/y_N$  need

not show symmetry properties such as were associated with these variables for cases I and II. These aspects as well as statistics for case IV are under detailed investigation and will be reported later.

## UPTAKE AND METABOLISM OF $^{14}\text{C}$ -LABELLED GLUCOSE IN *SARGASSUM ILICIFOLIUM*

C. A. GOWDA

Department of Botany, Rural College, Kanakapura, Bangalore District

### ABSTRACT

*Sargassum ilicifolium*, a common marine brown alga, shows the ability to take up glucose and metabolise it. Metabolism is greater in light than in darkness. The main products of metabolism are sugar phosphates, glutamate, aspartate and alanine and to some extent citrate, fucose, mannose, fucoidin, laminarin and alginate. Alginic acid biosynthesis starts later and is not possibly from mannitol. The alga probably belongs to a group of  $\text{C}_4$  plants of aspartate formers.

MARINE algae are well known for synthesising a wide range of complex organic compounds. In order to study metabolic pathways of these organic compounds, several attempts<sup>1-3</sup> have been made to feed marine algae with labelled compounds which are suspected to be the precursors. In the

light of these observations, it was thought that an experiment of feeding uniformly labelled glucose- $^{14}\text{C}$  to *Sargassum ilicifolium* could be designed.

### MATERIALS AND METHODS

*S. ilicifolium* was collected at low tides from sea-shores of Ratnagiri and placed in sea water.

\* Ethanol insoluble fractions.

— Activity not recorded.

The plants were washed first in filtered sea water and then in synthetic sea water<sup>4</sup>. The experiments of 30 minutes, 2 hours and 6 hours were carried out in two sets either in light or in darkness. The samples weighing 4 g were cut into small squares. The algal material was taken in an Erlenmeyer flask and floated in 60 ml of 0.025 M glucose solution (pH 8.0) prepared in synthetic sea water. The reaction was initiated by adding 0.02 mc of glucose- $^{14}\text{C}$  (specific activity 280 mc/mM). Experiments under light were performed by supplying illumination of about 4000 ftc near the algal material. Temperature was maintained between 15° C and 20° C. The flask was continuously shaken. The reaction was terminated by the addition of boiling 80% ethanol.

The material was homogenised and the extract filtered. The residual solids were analysed according to the method described by Bidwell<sup>5</sup>. The radioactivity of individual insoluble fractions was determined.

The combined filtrate was evaporated under reduced pressure to 5 ml and electrolytically desalted. The extract was analysed for ethanol soluble fractions by two-dimensional paper chromatography employing phenol : water (80 : 20 v.v) and butanol : acetic acid : water (80 : 22 : 50 v.v.v) as solvents. The radioactive compounds were detected by exposing the chromatograms to X-ray films. The activity incorporated in individual compounds was counted with a transistorised proportional counting system and confirmed with a liquid scintillation system.

## RESULTS AND DISCUSSION

Table I represents soluble as well as insoluble fractions and their radioactivity as counts per minute in 4 g of fresh tissue. A close scrutiny of autoradiograms revealed that glucose was gradually utilized. The utilization of glucose was more in light than in darkness. As a result of the utilization of glucose, sugar phosphates, amino acids and organic acids could be detected in the soluble fraction. In the soluble fraction, besides glucose, two spots in the sugar area had also shown incorporation of radioactivity. In the soluble fraction, incorporation was slow and alginic acid had little incorporation and that too only after 6 hours, while fuccidin and laminarian incorporated  $^{14}\text{C}$  from 30 minutes onwards. The results can be favourably compared with those of Lin and Hassid<sup>3</sup>.

The results are on similar lines and indicate that in *S. ilicifolium* sugar phosphates are formed by glucose utilization. This will obviously require phosphorylation and it appears enzymes similar to those present in *F. gardneri* may also be operating in *S. ilicifolium*. No label could be detected in mannitol, which possibly indicates that glucose is not the precursor of this important sugar alcohol in the brown alga. This observation is similar to that of Lin and Hassid<sup>3</sup>.

The incorporation of radioactivity into glutamate, aspartate and alanine clearly indicates that these were the major amino acids formed. This is similar to the result obtained by Bidwell and Ghosh<sup>2</sup>. From the recent unpublished work on photosynthesis of *Sargassum*, a good amount of radioactivity

was located in these amino compounds. Bidwell and coworkers<sup>4</sup> found out that in wheat leaves, when radioactive glucose was supplied, alanine became much more radioactive in light than in darkness. This was attributed to blockage of the carbohydrate respiration. It was possible for them to reverse blockage by the application of amino acids intrusion. The observation of more radioactivity in darkness is similar to that of Bidwell *et al.*<sup>5</sup>. However, whether it is respiration blockage cannot be ascertained with the present data.

Bidwell and Ghosh<sup>2</sup> have found that uniformly labelled glucose <sup>14</sup>C is utilized by *F. vesiculosus*. They have indicated several pathways of glucose utilization involving carboxylation and decarboxylation reaction. They notice that organic acids are better substrates for alginic acid than glucose. These authors also did not record any activity in mannitol but recorded it in fucose. From Table I, it is clear that activity in fucose fraction is higher at 6 hours than at half an hour. It is of interest to record the highest activity in citrate as noted by Bidwell and Ghosh<sup>2</sup>. However no explanation for this can be given with the present data. From Table I, it is also clear that alginic acid synthesis starts much later. This observation indicates that in *Sargassum* alginic acid biosynthesis starts later and

it is possibly from sugar phosphates as proposed by Lin and Hassid<sup>3</sup>.

In the present investigation, it is of interest to record an appreciably high label in aspartate and no label in malate. This, in the light of recent work of Karekar and Joshi<sup>7</sup>, indicates that *S. ilicifolium* belongs to a group of C<sub>4</sub> plants of aspartate formers and possibly aspartate is a key compound from which many other metabolic products are formed.

#### ACKNOWLEDGEMENTS

The author is grateful to Prof. G. V. Joshi, Head of the Department of Botany, Shivaji University, for the guidance, providing the facilities and critically going through the manuscript. Thanks are also due to University Grants Commission for the award of a Research Scholarship.

#### PRELIMINARY OBSERVATIONS ON THE USE OF MARINE CATFISH PITUITARY GLANDS FOR INDUCED SPAWNING OF THE INDIAN MAJOR CARPS

T. J. VARGHESE, G. P. SATYANARAYANA RAO, K. V. DEVARAJ AND  
B. CHANDRASEKHAR\*

*College of Fisheries, University of Agricultural Sciences, Mangalore*

#### ABSTRACT

Major carps are not available in adequate numbers, especially along the coastal regions of the country, for collection of pituitary glands for large scale induced spawning of these species. Therefore, attempts were made to utilise the pituitary of marine catfish, which are landed in good numbers along the coastal areas, for induced spawning of the major carps. Two species of the major carps, namely, *Labeo rohita* and *Cirrhina mrigala*, were successfully spawned during July, 1973 by administering intramuscular injections of pituitary extract of two species of marine catfish, *Tachysurus thalassinus* and *T. jella*. Sixtyfour per cent of the treated carps spawned successfully when injected with 30 mg and 20 mg of marine catfish pituitary per kg body weight of female and male fish respectively.

#### INTRODUCTION

THE Indian major carps were successfully induced to breed by the administration of fish pituitary hormones in 1957 (Chaudhuri and Alikunhi, 1957; Alikunhi *et al.*, 1960; Chaudhuri, 1960). Since then, the induced breeding technique has been vastly improved and its use as a dependable method of pure fish seed production has spread

widely to all States of India. However, the quantity of fish seed produced in the country through this method in 1964-65 was only 1.57% of the total annual production (Anon., 1966). One of the reasons for this low percentage of fish seed produced through hypophysation technique is the shortage of carp pituitary glands, especially along the coastal areas. With a view to overcome this limitation, studies on the use of marine catfish pituitary glands for induced breeding of freshwater fishes were initiated at the College of Fisheries, Mangalore, in

\* Department of Fisheries, District Bijapur, Karnataka.

1972, when a freshwater catfish, *Clarias batrachus*, was spawned successfully by injection of pituitary extracts from a marine catfish, *Tachysurus* sp. (Devaraj *et al.*, 1972). Experiments were conducted to induce breeding in the major carps, *Cirrhina mrigala* and *Labeo rohita*, with injections of pituitary extracts from two species of marine catfish during July, 1973 and the results thereof are reported in this communication.

#### MATERIALS AND METHODS

The pituitary glands used for the experiments were collected from the marine catfish, *Tachysurus thalassinus* and *T. jella* caught off the South Kanara Coast. The glands were collected during the period 30-1-1973 to 2-2-1973, from specimens ranging in weight from 1.0 kg to 9.75 kg. About 97% of the donor catfish were in the I or II stages of sexual maturity. The glands were preserved in absolute alcohol and stored in a refrigerator.

The induced breeding experiments were conducted in the fish farm of the Tungabhadra Board (Karnataka State) during July 1973. The major carp brood fish used for the experiments were all farm-reared and belonged to the age groups of II to IV. The methods followed for the preparation of pituitary extract and administration of hormone were the same as usually practised for the breeding of major carps.

The water temperature during the experimental period ranged from 25.3°C to 27.7°C. The weather was mostly cloudy, with one or two showers during most of the days.

#### RESULTS

The results of the induced spawning experiments are presented in Table I. Seven females and eleven males of *mrigal* were treated with pituitary extract of the marine catfish. In all cases, except in one set, the female and male fish received a total of 30 mg/kg and 20 mg/kg body weight of pituitary glands respectively. In experiment No. 4, one set of *mrigal* was injected at a lower dose of 20 mg/kg and 15 mg/kg pituitary for the female and male fish respectively. Of the six *mrigal* which received the higher dose of pituitary, five spawned successfully, yielding over 20 lakhs of eggs with normal rates of fertilisation. The *mrigal* treated at a dose of 20 mg/kg did not spawn. During these experiments, it was seen, that pituitary extract prepared and kept in a refrigerator for 24 hours could also be successfully used. Along with the fish injected with the marine catfish pituitary, six females and eleven males of *mrigal* were also treated with carp pituitary extract in order to compare the results. Of these, four spawned successfully yielding a total of 16,28,000 eggs.

From Table I it is seen that all *rohu* females and males, except one set in experiment No. 7, received 30 mg/kg and 20 mg/kg body weight of catfish pituitary respectively. One set of *rohu*, in experiment No. 7, was injected at a lower dose of 20 mg/kg and 15 mg/kg body weight of pituitary for female and male fish respectively. Of the five *rohu* treated at the higher dose, two spawned successfully yielding 7,54,600 eggs, while that injected with the lower dose did not spawn. Along with this, four *rohu* administered carp pituitary hormones also spawned.

#### DISCUSSION

The present experiments clearly demonstrate that it is possible to use the pituitary of the marine catfish *T. thalassinus* and *T. jella*, for induced spawning of the Indian major carps. From Table I, it is clear that seven out of eleven females treated with the marine catfish pituitary extract at a dose of 30 mg/kg spawned. Two female fish, one *rohu* and one *mrigal*, injected at a lower dose of 20 mg/kg of pituitary, did not spawn. Among the ten control fish treated with carp pituitary, eight spawned, accounting for 80% of positive results.

Normally doses of 6 to 10 mg/kg for female and 4 to 6 mg/kg body weight for male fish are used for induced spawning of the Indian major carps, when pituitary extracts from mature carps are injected. The dosage of pituitary required to spawn major carps when the donor carps are immature is not known. During the present experiments it was not possible to work out the minimum threshold dose of pituitary of the marine catfish required for spawning of major carps. A higher dose of pituitary of the marine catfish was used deliberately in view of the immature condition of the donor fish and the phylogenetic and habitat differences between the donor and recipient species. Though it is reported that there is no great phylogenetic specificity between the pituitary hormones of different species of fishes (Pickford and Atz, 1957), some of the heteroplastic injections have failed to yield positive results. For instance, Clemens and Sneed (1962) have reported that extremely high doses of carpsucker (*Carpiodes carpio*) pituitaries were required to ovulate female goldfish. The Indian major carps could not be spawned by pituitaries of grey mullets (*Mugil cephalus* and *Liza troschelli*) and *Tilapia mossambica* (Anon., 1970). In view of the fact that the donor catfish in our experiments were mostly immature, it should be possible to spawn the major carps with a much lower dose by employing pituitaries of mature marine catfish.

On an average, the catfish, mainly represented by various species of *Tachysurus*, accounts for

TABLE I

M = Male; - = Negative response.

about 5% of the total marine fish landings of India. As the bulk of the catfish landed are used for sun-drying, for which the fish are split open, the fishermen may not object if the scalp is cut for the collection of pituitary glands. The cost of a major carp pituitary gland works out to about 50 paise, while it is only 10 paise in the case of marine catfish gland. Moreover, the major carps are scarce along most of the coastal areas. In this context,

the present finding should help not only in reducing the cost of fish breeding work, but also to solve the problem of shortage of carp pituitary at fish seed production centres.

## ACKNOWLEDGEMENTS

We are grateful to Shri H. P. C. Shetty, Director of Instruction, College of Fisheries, for the keen interest evinced in these experiments and for kindly

going through the manuscript and to Sarvaswari O. K. Ajjappa, B. M. Kotraiah and O. Bhavanishankar for extending all facilities in the field for conducting these experiments.

## RECENT TRENDS IN ELECTROCHEMICAL SCIENCE AND TECHNOLOGY

THE Society for Advancement of Electrochemical Science and Technology (SAEST) is a professional scientific body which was founded in 1965 at Karaikudi. It was started with a view to disseminating knowledge on Electrochemical Science and Technology. It publishes two journals, one quarterly Journal titled *Transactions of SAEST* and the other monthly *Current Titles in Electrochemistry*. In addition, the SAEST arranges joint symposia in collaboration with Electrochemical Industries, and these are held at the premises of the sponsoring industries. It also organizes Technical sessions every year on topics of current interest in the field of electrochemical science. To mark the completion of 10 years of its useful service, the Society observed its Decenary Celebrations on 26–27th November 1974 at Karaikudi.

A technical session on 'Recent Trends in Electrochemical Science and Technology' was got up for this occasion and it was primarily devoted to survey the status of Electrochemical Industries and their future prospects with particular reference to India. The recent developments in the field of Electrochemical Technology in India were also included in the scope of the session. The subjects covered were Chlor-alkali, Batteries, Electro-metallurgy, Electro-thermal products, electro-organic and inorganic chemicals, Metal finishing, and Anti-corrosion products. The venue for this seminar was Central Electrochemical Research Institute, Karaikudi, where the headquarters of the SAEST is located.

The symposium was organized under five sessions. In the first session on "Electro-organic and inorganic products", articles on 'Chloralkali Industry in India,

'Titanium Substrate Insoluble Anode for Chlor-alkali Cells', 'Inorganic Electrochemicals in India' and 'Electro-organic Products' were presented. The second session was devoted to 'Electrometallurgy' papers covering Lead, Zinc, Copper and Nickel. The third session on 'Electrothermics and fused salts' presented discussions on a number of electro-thermal products. During the fourth session, an account of the technology, production and growth of the Indian battery industry was presented. During the last session, the present Status and Modern Trends in Phosphating, a prepainting stage in the treatment for metals were discussed.

Three special lectures also formed part of the technical session. Prof. S. Ramaseshan gave a talk on 'Electrochemical Machining' describing the work currently carried out at the National Aeronautical Laboratory, Bangalore.

Prof. S. K. Rangarajan of National Aeronautical Laboratory, Bangalore, in his lecture on 'Perspectives in Fundamental Investigations' presented the basic approaches for evaluating typical problems of technological importance such as dendritic growth of zinc, optimization of cell design in electrochemical reactors. Finally Prof. K. S. G. Doss, the Founder President and former Director of Central Electrochemical Research Institute lectured on the principles of metal corrosion.

The session was attended by well over 230 delegates from all over the country including a number of representatives from industries and Governmental bodies and brought to focus the recent developments, existing problems and future projections relating to electrochemical industries in India.

## INTERNATIONAL SYMPOSIUM ON BIOLOGY AND MANAGEMENT OF MANGROVES

**A**N International Symposium on the Biology and Management of Mangroves was held at East-West Centre, Honolulu, Hawaii (U.S.A.) from October 8 to 11, 1974. It attracted participants and observers from all over the world including UNESCO. There were 13 sessions which dealt with general aspects of mangroves, geomorphology, biogeography, soils, chemical elements, micro-organisms, physiology, estuaries, communities, systems and synthesis. The management aspects were also covered. About 70 papers were read and discussed.

An interesting feature of the Symposium was the formation of small working groups from among participants. The groups were assigned to list priorities in mangrove research and management. The recommendations of the various groups were gathered, processed and forwarded to the UNESCO-SCOR for further action. A proposal was mooted for an international society for the study of mangroves, and later, promotion of a journal to bring various mangrove-related publications under one roof. It is hoped that this proposal will be taken up seriously in due course.

The Symposium concluded with passing a resolution addressed to the Secretary-General, U.N.O.

It emphasized the catholicity of world's mangrove ecosystems as "valuable resources and .... governments be urged to promote research to better appraise these ecosystems and .... exert special care when evaluating actions or proposals that could commit these resources".

We are indebted to Dr. A. G. Pawar, Vice-Chancellor, Shivaji University, Dr. S. P. Adinarayana, Vice-Chancellor, Annamalai University and Dr. R. Natarajan, Director, Centre of Advanced Study in Marine Biology of Annamalai University, Porto Novo, for their keen support and encouragement; and to the authorities of the respective Universities for permission to their staff to participate as delegates in the Symposium.

## CURRENT SCIENCE

*Fortnightly Journal of Research*

Issued on the 5th and 20th of each month

### IMPORTANT NOTICE TO SUBSCRIBERS OF THE JOURNAL

As you are aware CURRENT SCIENCE has been coming out regularly on the due dates as above with the kind co-operation of you all.

On account of the sharp increase in the cost of quality paper used for the Journal, increase in rates of block making materials, increase in postal rates and the increase in the establishment charges it has become impossible for the Association to issue the Journal, unless the subscription rates are put up.

The Working Committee of the Association has reluctantly decided at its last meeting, to enhance the subscription of CURRENT SCIENCE with effect from 1st January 1975 for institutions :

India Rs. 84/- Foreign Rs. 150.00 \$ 20.00 or £ 8.0.0

The subscription rates for individual subscribers however will remain the same as now.

The continued co-operation of our subscribers is requested.

Bangalore-6  
30th July 1974

## LETTERS TO THE EDITOR

ANALYTICAL APPLICATIONS OF 5-ETHYL  
RESACETOPHENONE OXIME (5-ERAPO)

## Gravimetric Determination of Copper

5-ETHYL resacetophenone oxime (5-ERAPO) has been found to be a suitable chelating agent for gravimetric determination of copper. The reagent reacts quantitatively with Cu(II) in the pH range 3.5 to 9.0 giving an insoluble metal complex. The buff coloured copper complex can directly be weighed as  $\text{Cu}(\text{C}_{10}\text{H}_{12}\text{O}_3\text{N})_2$  after drying at  $110^\circ$  to  $120^\circ\text{C}$ , the error being less than  $\pm 0.3\%$ . The reagent gives pale green precipitate with Ni(II) at pH 5.0, orange yellow precipitate with Co(II) at pH 6.5 and violet colour with Fe(III) at pH 2.5 to 4.5. The interference due to several ions such as Ca(II), Ba(II), Sr(II), Mg(II), Ni(II), Co(II), Zn(II), Al(III) has been avoided by working at controlled pH, and by using suitable masking agent. The accuracy in the above case is  $\pm 0.7\%$ .

The reagent<sup>1</sup> was prepared as follows:

4-Ethyl resorcinol (7.5 gm), obtained by the Clemmensen's reduction of resacetophenone, was heated with fused zinc chloride (20 gm) in glacial acetic acid (30 ml). The reaction mixture was boiled and then cooled to room temperature. This reaction mixture was cooled with ice after the addition of 100 ml of cold 50% HCl. The product 5-ethyl resacetophenone (5.2 gm) was crystallised from hot benzene (M.P.  $119^\circ\text{C}$ ), its oxime was prepared by the usual method and crystallised from hot water (M.P.  $141^\circ\text{C}$ ).

The copper bischelatate  $\text{Cu}(\text{C}_{10}\text{H}_{12}\text{O}_3\text{N})_2$  (Cu calculated 14.06%, found 13.92%) with the reagent precipitated at pH 3.5 is buff coloured and is insoluble in water, 40% ethanol, ether and dilute acetic acid; but it is soluble in chloroform and ethanol.

**Procedure for determination of Cu(II).**—An aliquot standard solution of Cu(II) containing 15 to 63 mg metal was diluted to 200 ml and pH was adjusted using acetate buffer. The solution was warmed to  $60^\circ$  and 1.0% ethanolic solution of the reagent was added with constant stirring till it was 10% excess over the calculated amount. The precipitate was digested at about  $60^\circ$  and allowed to stand for about 30 min. It was filtered through a sintered glass crucible (G4), washed with 40% ethanol to remove excess reagent, dried at  $110^\circ$  to  $120^\circ\text{C}$  to constant weight and finally weighed as  $\text{Cu}(\text{C}_{10}\text{H}_{12}\text{O}_3\text{N})_2$ . The gravimetric factor

(copper/copper complex) is 0.1407. The results are given in Table I.

TABLE I  
Determination of copper

| Cu(II) mg<br>(taken) | Cu(II) mg<br>(found) | %<br>(error) |
|----------------------|----------------------|--------------|
| 7.85                 | 7.80                 | -0.64        |
| 15.71                | 15.68                | -0.19        |
| 31.43                | 31.50                | +0.22        |
| 47.14                | 47.24                | +0.21        |
| 62.86                | 62.72                | -0.22        |

**Determination of copper in presence of other ions.**—The pH range at which the precipitation of Ni(II) and Co(II) takes place is higher than that for the precipitation of Cu(II). It was therefore possible to determine Cu(II), (30 mg) at pH 3.5 in the presence of an equal amount of Ni (% error 0.2) and Co (% error 0.7). Zn(II), Mg(II), Ba(II), Ca(II), Sr(II) were found to give no colour nor an insoluble chelate. Hence copper could be determined in presence of these ions with a maximum error of 0.7%. Ferric (III) interferes during the precipitation of copper (II); however the determination was carried out sequestering Fe(III) by potassium citrate.

REACTION ON BIS-FORMAMIDINE  
DISULPHIDE WITH INDOLE

WITH a view to extending the reaction<sup>1</sup> of bis-formamidine disulphide dihydrobromide I, to reactive aromatic systems other than phenols, the reaction of I with indole was investigated. Indole 1.2 g was heated with 3.1 g of I at  $60^\circ$  for 30 minutes. The reaction mixture was cooled, triturated with water and filtered when a dry white hydrobromide 1.9 g (70%) was obtained, crystals from warm, dil. HBr, m.p.  $217-219^\circ$  (decomp.) (Found: C, 40.12; H, 4.08; N, 15.11%. Required for  $\text{C}_9\text{H}_{10}\text{N}_3\text{SBr}$ : C, 39.70; H, 3.67; N, 15.44%).

The n.m.r. spectrum of the hydrobromide in  $D_2O$  n.m.r. frequencies showed multiplets as expected, in 7.3–7.9  $\delta$  region for all the aromatic protons of indole, the other protons attached to nitrogen showing no peaks due to exchange with  $D_2O$ .

The most probable site in indole for attack of the sulphenium ion,  $\oplus S-C-NH_2$ , is the 3 position,

resulting in the formation of the hydrobromide II. That the hydrobromide was not a disulphide of the type III could be seen by its lack of reactivity aq. KI and aq.  $H_2S$  solution<sup>1</sup>.

The II on treatment with cold dil. alkali immediately precipitated a pale yellow solid which darkened on exposure to air. The sulphides of the type IV are known<sup>1</sup> to decompose in alkaline solution to thiols, which slowly get oxidised to disulphides. The dark coloured solid from II had m.p. 90–110°; the thiol from the corresponding hydriodide of II obtained under nitrogen atmosphere is reported<sup>2</sup> to melt at 99–100°. The dark solid (the m.p. of which kept rising on keeping) on shaking with  $H_2O_2$  for an hour, gave a white solid; crystallised from dil. ethanol, m.p. 214–217°; reported<sup>2</sup> m.p. for disulphide VI is 218–220°.

The II on Schotten Baumann benzoylation gave a pale yellow crystalline benzoate V, m.p. 144–145° (from ethanol), (Found S, 12.03; calc. for  $C_{15}H_{11}NOS$  12.64%); the reported<sup>2</sup> m.p. for the benzoate V is 142–144°. That the sulphur was linked at the 3 position of the indole was demonstrated by the earlier workers<sup>3</sup>.

Thanks of the author are due to the authorities of Banaras Hindu University for providing the facilities and to the C.S.I.R. for the award of Post Officership (1971–73).

### ANALYTICAL APPLICATIONS OF 2-AMINO-5-NITROSO-4, 6-PYRIMIDINEDIOL

CONTINUING the work<sup>1,2</sup> on analytical applications of pyrimidinols, in the present note the potentialities of the compound 2-amino-5-nitroso-4, 6-pyrimidinediol (ANP) are described. ANP reacts with  $Fe^{2+}$  and  $Ru^{3+}$  giving respectively blue and pink colorations suitable for their determination. The yellow complex obtained with  $Co^{2+}$  solution is also of analytical interest.

ANP was obtained from K & K Laboratories, U.S.A. Its standard solution (0.004 M) was prepared by dissolving 624 mg of the compound in 1 litre of double distilled water (hot). The stock solutions of  $Fe^{2+}$ ,  $Ru^{3+}$  and  $Co^{2+}$  were prepared by dissolving appropriate amounts of Mohr's salt in double distilled water, ruthenium chloride in 1 M-HCl and cobalt metal in dilute HCl. To Mohr's salt solution, few ml of 1% hydroxylamine hydrochloride were added to prevent oxidation of  $Fe^{2+}$  to  $Fe^{3+}$ . The solutions were standardized by gravimetric methods.

The aqueous solution of ANP is light red in colour, absorbing maximum at 255 ( $\epsilon = 2800$ ) and 315 nm ( $\epsilon = 840$ ). The characteristics of the complexes formed with  $Fe^{2+}$ ,  $Ru^{3+}$  and  $Co^{2+}$  salt solutions are summarized in Table I. Because of the intensity of the colours of iron (III) and ruthenium complexes, they were used in spectrophotometric determination of the two metals.

**Procedure for determination of iron.**—To a suitable aliquot of iron (II) solution, add 5.0 ml of ANP solution followed by 4.0 ml of sodium acetate-hydrochloric acid buffer solution (pH 5.0). Make up the volume and measure the absorbance of the blue solution at 640 nm against reagent blank. Calculate the amount of iron by comparing the absorbance with a calibrated curve.

**Procedure for determination of ruthenium.**—To a suitable aliquot of ruthenium solution, add 8.0 ml of ANP solution followed by 4.0 ml of acetate buffer (pH 5.0). Heat the solution on steam bath for one hour, cool it and make up the volume. Note the absorbance of the pink solution at 517 nm

#### INTERACTION OF BILIRUBIN WITH HUMAN ERYTHROCYTE MEMBRANE\*

BILIRUBIN reaches toxic levels in icteric newborns (hyperbilirubinemic newborns) especially in "Kernicterus" and causes irreversible nuclear damage of brain and other tissues<sup>1,2</sup>. It has been shown earlier that bilirubin interferes with the fragility of human erythrocytes<sup>3</sup>. The present report deals with the binding of bilirubin to human erythrocyte membranes.

Tritium labelled bilirubin prepared by Wilzbach procedure as described by Grodsky *et al.*<sup>4</sup> was supplied by Isotope Division of Bhabha Atomic Research Centre, Trombay, India. The preparation was purified to constant specific activity (7  $\mu\text{Ci}/\mu\text{mol}$ ) as described by Kapoor *et al.*<sup>5</sup>. Washed erythrocytes were prepared from the blood of healthy donors from the Blood Bank of K.G.'s Medical College, Lucknow<sup>6</sup>. Human erythrocytes ( $1 \times 10^9$  cells) were incubated in a metabolic shaker 40 strokes/min (ampl: 2 cm) at 25°C for 30 min, in a 3 ml incubation medium containing Tris HCl buffer pH 7.5 (8.1 mM) and sodium phosphate buffer pH 7.5 (8.1 mM) with varying concentrations of <sup>3</sup>H-bilirubin, in presence or absence of different amounts of albumin precalculated to give varying bilirubin : albumin molar ratios.

After incubation cells were washed free from media and dispersed in hypotonic sodium phosphate buffer pH 7.5, incubated at 5°C for 30 min and

centrifuged at  $20,000 \times g$  at  $5^\circ C$  for 30 min. The ghosts containing bilirubin were dispersed in hypotonic buffer and the suspension again centrifuged at  $20,000 \times g$  for 30 min. The supernatant fluid was recovered carefully by aspiration.  $^3H$ -bilirubin was extracted from erythrocyte ghosts and hemolysate with chloroform and methanol (2:1 v/v) and dried *in vacuo*. Aliquots of dried samples were suspended in vial containing 15 ml of scintillation fluid 0.4% (w/v) 2,5, diphenyl oxazol (POP) and 0.04% (w/v) [1-4-bis-2-(Methyl-5-phenyl-oxazolyl)-benzene] (POPOP) in distilled toluene, and the radioactivity of the samples measured in low  $K^+$  vials. The efficiency of the Packard Tricarb Scintillation Spectrometer was of the order of 40 to 43% for  $^3H$  as measured by using *n*-hexadecane 1.2 T (Amersham, Bucks, U.K.) as internal standard.

In blood, bilirubin is firmly bound to serum proteins relatively strongly to albumin<sup>6</sup>. This mechanism protects the cells as long as the molar ratio of bilirubin to albumin is less than 1:17.8. Since the determination of erythrocyte bound bilirubin could be of clinical significance in cases of neonatal jaundice<sup>9-10</sup>, attempts were made to confirm the interaction of bilirubin with erythrocytes by conducting binding studies with  $^3H$ -bilirubin and erythrocyte at different molar ratios of bilirubin to albumin. The results presented in Table I

TABLE I

*Binding of bilirubin to erythrocytes at different molar ratios of bilirubin to albumin*

Erythrocyte ( $1.0 \times 10^9$  cells) were incubated in 3 ml incubation medium (pH 7.5) with different molar ratios of bilirubin and albumin at  $25^\circ C$  for 30 min in a metabolic shaker. The total  $^3H$ -bilirubin concentration was kept constant ( $0.2 \mu$  mole containing  $55.5 \times 10^3$  cpm). After incubation cells were washed free from medium and bilirubin bound to erythrocytes were extracted and radioactivity of samples were counted in Packard Tri-Carb Scintillation Counter as described in the Method.

| Molar bilirubin/<br>albumin ratios | cpm $\times 10^{-3}/10^9$ cells |                         |
|------------------------------------|---------------------------------|-------------------------|

| 0.5                                | 9.33                            | 12.27                   |
| 1.0                                | 10.12                           | 14.29                   |
| 1.5                                | 13.24                           | 19.30                   |
| 2.0                                | 18.17                           | 22.03                   |

indicate that greater binding of bilirubin to erythrocytes takes place, when molar ratio of bilirubin to albumin exceeds 1:1. However, a small amount of bilirubin is associated with erythrocytes

even at a molar ratio below 1:1. Human serum albumin (HSA) is more effective in protecting the binding of  $^3H$ -bilirubin to erythrocytes than bovine serum albumin (BSA), i.e., due to greater binding capacity of HSA for bilirubin. The association of bilirubin at molar ratio below 1:1 of bilirubin to albumin can be due to a finite number of "attachment sites" on human erythrocyte surface for albumin<sup>11</sup>. From studies of the pattern of distribution of  $^3H$ -bilirubin, picked up by erythrocytes between organelles and cytosol, more than 85% bilirubin taken up by erythrocytes appears in membrane fraction (Table II). By exhaustive

TABLE II

*Distribution of  $^3H$ -bilirubin in membrane and soluble fraction of erythrocyte*

Human erythrocytes ( $1.0 \times 10^9$  cells) were incubated in increasing  $21$ – $170 \mu M$  ( $17.3 \times 10^3$ – $13.8 \times 10^4$  cpm) concentration of  $^3H$ -bilirubin in 3 ml incubation medium (pH 7.5) at  $25^\circ C$  for 30 min, washed free from medium and  $^3H$ -bilirubin in erythrocyte ghosts and hemolysate was extracted with a mixture of chloroform and methanol (v/v 2:1); the solvent extract was dried *in vacuo* and radioactivity of the dry samples counted in vials containing scintillation fluid in a Pack Card Tri-carb Scintillation Spectrometer as described in Experimental Section.

extraction of erythrocyte ghosts with mixture of chloroform : methanol (2:1 v/v) almost all the radioactivity was recovered along with the lipid and the residual ghost had only negligible radioactivity. These results indicate that sites are located on erythrocyte membrane and these account for the binding of bilirubin to erythrocyte even at molar ratio below 1:1 of bilirubin to albumin. Evidently, lipids are responsible for the binding.

The author wishes to record his appreciation to Dr. C. R. Krishna Murti for most valuable guidance and many thoughtful suggestions. Thanks are due to Mr. S. Dey and Dr. S. K. Roy of Endocrinology

Division for their help in counting the radioactive samples.

### LYSOGENIC CONVERSION IN *SERRATIA MARCESCENS*

LYSOGENISED cells sometimes show modification of one or more host properties. The production of toxin by *Corynebacterium diphtheriae* is perhaps the most striking example. The presence of a particular prophage in *B. megaterium* has been reported to modify colonial morphology<sup>2</sup>. In the genus *Salmonella*, the capacity to form new somatic antigens is conferred by presence of certain prophages. Loss of the antigenic determinants is always found to be associated with loss of the prophage<sup>3</sup>. Phage conversion involving an alteration of somatic antigens has also been reported in *Pseudomonas aeruginosa*<sup>4</sup>. In *Staphylococci*, alterations in phage typing pattern, susceptibility to penicillin and the capacity to produce toxin are affected by lysogenization with appropriate phage<sup>5</sup>. In *Bacillus cereus* lysogeny and toxinogeny also appear to be interdependent<sup>6</sup>.

Lysogenic conversion resulting in altered enzymic activity has been reported in *Mycobacterium smegmatis*<sup>7</sup>.

In the present investigation we report changes in pigment production by nonlysogenic *Serratia marcescens* versus *Serratia marcescens* lysogenised by phage kappa.

TABLE I

Phage resistance pattern of lysogenic and non-lysogenic strains of *S. marcescens*

| Strain       | Plaque count per ml |
|--------------|---------------------|
| Nonlysogenic | $5.4 \times 10^8$   |
| Lysogenic    | Nil                 |
| Nonlysogenic | $1 \times 10^8$     |
| Lysogenic    | Nil                 |
| Nonlysogenic | $5.2 \times 10^8$   |
| Lysogenic    | Nil                 |

The original phage suspension was diluted in phosphate buffer and then 0.1 ml of the diluted suspension taken for plaque count on nutrient agar using as the plating organism 1 ml of 24 hrs culture of *S. marcescens* and its lysogenic strain.

TABLE II

Effect of U-V exposure on the lysogenic and non-lysogenic strains of *S. marcescens*

| Time of exposure | Plaque count per ml |              |
|------------------|---------------------|--------------|
|                  | Lysogenic           | Nonlysogenic |
| 30 sec           | $120 \times 10^4$   | Nil          |
| 1 min            | $140 \times 10^6$   | "            |
| 5 min            | $210 \times 10^6$   | "            |
| 15 min           | $790 \times 10^6$   | "            |
| 30 min           | $122 \times 10^7$   | "            |

5 ml of cell suspension in nutrient broth of lysogenic and nonlysogenic *S. marcescens* taken in a petridish was irradiated with a Philips U.V. lamp from a distance of 15 cm. Then the treated suspension was plated (0.1 ml) on *S. marcescens* as the indicator organism (1 ml of 24 hrs culture).

TABLE III

Pigment production by lysogenic and nonlysogenic strains of *S. marcescens*

| Expt. No. | Strain       | Wt. of the cell/10 ml | Pigment content/5 ml of cultures expressed as Klett-Reading at 540 mμ |
|-----------|--------------|-----------------------|---|
| 1         | Nonlysogenic | 0.0085                | 110   |
|           | Lysogenic    | 0.0085                | 185   |
| 2         | Nonlysogenic | 0.0085                | 110   |
|           | Lysogenic    | 0.0085                | 185   |
| 3         | Nonlysogenic | 0.0085                | 110   |
|           | Lysogenic    | 0.0085                | 185   |

50 ml of nutrient broth taken in a conical flask was inoculated with the strains of *S. marcescens* and incubated for 10 days at 30° C. An aliquot of 40 ml was then worked up for pigment production according to the method of Williams, Green and Rapport<sup>8</sup>. Another aliquot of 10 ml was used to get dry weight of cells,

The lysogenic strain was isolated from a turbid plaque obtained by plating on the nonlysogenic strain the temperate phage *kappa*. The isolate was tested for its phage resistance pattern (Table I), U.V. induction of lysis (Table II) and pigment production capacity (Table III). The pigment produced was also subjected to spectral analysis at neutral, acidic and alkaline pH using 3 ml of alcoholic extract and adding 0.3 ml of 1 N HCl or 1 N NaOH for acidic or alkaline pH.

Table I shows that the isolate resists lysis when the phage *kappa* was plated on it. On exposure to U.V. the isolate produces plaque (Table II) while the parent nonlysogenic strain fails to do so under similar conditions. Thus the isolate is a true lysogen and not a phage resistant mutant of *S. marcescens*.

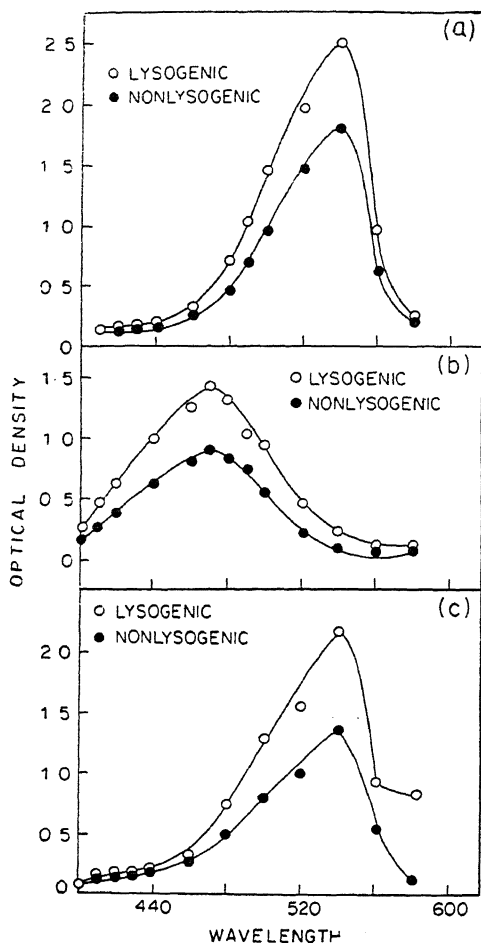

FIG. 1. Absorption spectrum in the visible range under acidic (a), alkaline (b) and neutral (c) condition of the pigment synthesised by lysogenic and nonlysogenic strain of *S. marcescens*.

Table III shows that pigment produced by the lysogen is almost double the amount produced by the nonlysogen. The increased pigment production is not due to cell mass since the cell mass for the lysogenic as for the nonlysogenic strain is nearly the same. Moreover Figs. 1 and 2 show that there is no appreciable changes in the spectral behaviour of pigments, which suggests that the nature of pigment synthesised by both lysogenic and nonlysogenic strains may be the same. Lysogenic conversion with respect to pigment production is thus indicated.

FIG. 2. U.V. absorption spectrum under acidic (a), alkaline (b) or neutral (c) condition of the pigment synthesised by lysogenic and nonlysogenic strain of *S. marcescens*.

#### EFFECT OF GIBBERELIC ACID ON ALPHA AMYLASE ACTIVITY OF MUTAGEN-TREATED BARLEY SEEDS

GIBBERELIC acid ( $GA_3$ ) is known to enhance the alpha amylase activity in the endosperm of barley seeds and other grain crops. Ananthswamy, 1971 in wheat; Muller, 1971 in pea; Palge, 1960 in barley; Varner, 1964 in barley. However, it is not known if gibberellic acid will have any modifying effect on the alpha amylase activity of mutagen treated barley seeds. In the present investigation, the effect of gibberellic acid on seeds treated with mutagenic agents, viz., ethyl methane sulphonate (EMS), methyl methane sulphonate (MMS) and gamma rays (Kr) was investigated.

Irradiation of barely, seeds, variety RS 6, was done in the Division of Genetics, Indian Agricultural Research Institute, Delhi. Treatment of seeds with EMS and MMS (Eastman Kodak Company, U.S.A.) was done by dissolving different concentrations of the mutagens in 0.02 M phosphate buffer at pH 6.9. Seeds were first soaked in different concentrations of EMS and MMS for 10 hours after which these were washed several times with distilled water and then placed in 1000 ppm gibberellic acid solution (Phylaxia, Budapest) for 8 hours.

Gibberellic acid (1000 ppm) was prepared by dissolving 0.1 gm of gibberellic acid in one ml absolute alcohol and volume made up to 100 ml with distilled water. Irradiated seeds were also treated similarly by soaking in distilled water for 12 hours, after which these were taken out and placed in gibberellic acid solution for 8 hours.

From each treatment, 0.5 gm of the seed was taken and ground in a pestle and mortar with 15 ml of 0.02 M phosphate buffer (pH 6.9) at 8° C and filtered through Whatman No. 1 filter-paper, following the method of Bernfield, 1960. One ml of this filtrate was made up to 25 ml with distilled water, which was incubated for three minutes at 20° C, after mixing with one ml of 1% starch. The enzyme reaction was interrupted by

the addition of 2 ml of 3-5-dinitrosalicylic acid and was heated for 5 minutes in boiling water and then cooled in running tap water. After the addition of 15 ml of distilled water, the optical density of the solution containing the brown reduction product was determined at 540 m $\mu$  using Spectronic-20. The blank is prepared in the same manner without adding enzyme preparation. A calibration curve established with maltose was used to convert the reading of optical density into milligrams of maltose.

The alpha amylase activity is expressed in terms of milligrams of maltose liberated in three minutes at 20° C by 1 ml of the enzyme solution of mutagen and gibberellic acid treated barley seeds.

Irradiated barley seeds with different dosage of gamma rays and then treated with gibberellic acid were analysed for alpha amylase activity. Twenty seeds were used for each treatment. In control, the seeds were treated with distilled water and gibberellic acid.

TABLE I  
Effect of gibberellic acid (1000 ppm) on alpha amylase activity of irradiated seeds

| Treatment                   | Enzyme Activity<br>(mg of maltose)<br>in (Kr) treated<br>seeds | Enzyme Activity<br>(mg of maltose)<br>in (Kr - Gibbe-<br>rellic acid)<br>treated seeds |
|-----------------------------|--|--|
| 20 Kr                       | 0.5  | 0.71   |
| 30 Kr                       | 0.43   | 0.55   |
| 40 Kr                       | 0.38   | 0.5  |
| 50 Kr                       | 0.29   | 0.38   |
| Control—water               | 0.58   | ..   |
| Control—gibberellic<br>acid | 0.82   | ..   |

In Table I, it is indicated that gibberellic acid increases alpha amylase activity in both irradiated and controlled barley seeds. However, with increased dosage of irradiation, there is a corresponding decrease in the enzyme activity.

In Table II, it is found that there is a reduction in the alpha amylase activity when barley seeds are treated with the mutagenic agents EMS. But when such seeds are treated with gibberellic acid ( $GA_3$ ) for 8 hours, the alpha amylase activity increases.

The effect of gibberellic acid on the recovery of the enzymatic activity of the irradiated barley seeds is 90% higher at 20 to 50 Kr. But it decreases as the Kr dosage increases. There is not much recovery of the enzyme activity in the case of EMS and MMS treated barley seeds. It is also seen that

TABLE II

Effect of gibberellic acid ( $GA_3$ ) on alpha amylase activity of EMS and MMS treated barley seeds

| Concentration %          | Enzyme Activity (mg of maltose) in MMS and EMS treated seeds | Enzyme Activity (mg of maltose) in $GA_3$ + MMS and EMS treated seeds |
|--------------------------|--|---|
| <b>MMS</b>               |  |   |
| 0.0125                   | 0.32   | 0.38  |
| 0.025                    | 0.29   | 0.33  |
| 0.05                     | 0.25   | 0.27  |
| 0.075                    | 0.22   | 0.23  |
| <b>EMS</b>               |  |   |
| 0.125                    | 0.37   | 0.45  |
| 0.25                     | 0.35   | 0.38  |
| 0.5                      | 0.29   | 0.35  |
| 0.75                     | 0.19   | 0.30  |
| Control—water            | 0.58   | ..  |
| Control—gibberellic acid | 0.82   | ..  |

the damage to the enzyme activity, caused by the irradiation of the seeds, is different with the EMS and MMS treated barley seeds. However, the possibility of a higher recovery of the enzyme activity in EMS and MMS treated barley seeds by increasing the amount of gibberellic acid ( $GA_3$ ) may exist and work is in progress.

#### A NOTE ON THE ORIGIN OF LEPTYNITES

THE frequent occurrence of leptynites (garnetiferous quartzo-feldspathic granulites) and khondalites in association with the charnockite suite of rocks is interesting from the point of view of their origin. While khondalites have been proved to be definite metamorphosed pelites, opinions differ with regard to the premetamorphic origin of leptynites and there are arguments in favour of ortho, para, as

well as migmatitic origin for these rocks. While Holland<sup>1</sup> regarded leptynites as products of dynamo-metamorphosed charnockites, Subramanyam<sup>6</sup> regarded the leptynites of Madras area to be an intensely metamorphosed recrystallised and reconstituted facies of khondalites. On the other hand Viswanathan *et al.*<sup>8</sup>, Narayanaswamy<sup>4</sup> and Ramaswamy *et al.*<sup>5</sup> have argued in favour of migmatitic origin for these granulites.

Leake<sup>2</sup> has deduced certain critical diagnostic graphs which involve Niggli mg, C, al-alk and trace elements Ni and Cr, in order to discriminate between ortho and para amphibolites. Van de Kamp<sup>7</sup> used these diagrams to study the premetamorphic origin of metasediments in Haliburton, Madoc area, SE Ontario. The critical graphs are plot of Niggli mg against C, C against al-alk, trilinear 100 mg, C, al-alk where  $mg + C + (al-alk) = 100$ , mg against Cr, and mg against Ni.

FIG. 1. Niggli C against mg plot. The dashed curve outlines the pelite area and the thick line indicates the igneous trend of variation—from Van de Kamp<sup>7</sup>. The plot of leptynites spread between igneous line and field of pelites.

The behaviour of these elements is unusually sensitive and diagnostic of the rocks. When they are plotted for a range of igneous and sedimentary rocks they fall in markedly different fields and show definite trends of variation. The reliability of the criteria is demonstrated by Leake<sup>2-3</sup>. The authors in the present paper have attempted to extend these criteria in order to understand the premetamorphic origin of the leptynites. Eighteen analyses of leptynites are plotted. Twelve of them were collected from the literature<sup>5-9</sup> (Puri Dist.—1, Madras—4, Capecomorin—3, Palani—1, and Guntur Dist.—3). Six fresh analyses were carried out, three

each from Madras and Niligiri areas, for major elements and traces Ni and Cr. Figures 1, 2 and 3 are reproduced from Van de Kamp<sup>7</sup> to show different fields of igneous and sedimentary rocks and trend of their mixtures. The analyses of leptynites are plotted on these diagrams.

FIG. 2. Plot of C against al-alk. The differences between the igneous trend and those for pelite-carbonate mixtures are shown—from Van de Kamp<sup>7</sup>. The leptynite plots trend between low C and al-alk field and field of pelites.

FIG. 3. Triangular plot C, al-alk, and 100 mg indicating the igneous trend obtained for Karoo dolerites and those to be expected for pelite-carbonate mixtures. Reproduced from Van de Kamp<sup>7</sup>. The leptynite plots lie between the igneous line and field of pelites and semipelites.

Figure 1 is the plot of Niggli mg against C. The thick curve indicates the trend of igneous differentiation for Karoo dolerites<sup>2</sup>. The dotted line encloses the field of pelites and semipelites. The plots of leptynites (except one) scatter between the pelite field and the line of igneous differentiation. The same situation is observed in Fig. 3, where Niggli mg, C and (al-alk) are plotted on a trilinear diagram where once again they are distributed between the pelite field and the igneous line. Figure 2 is more

critical where the slope of the leptynite plot shows a negative correlation and trends against the line of igneous differentiation. It extends between the low C and al-alk region and the field of pelites. This suggests that the leptynites were either original pelites mixed with psammites or arkoses, or they were original pelites into which there was feldspathisation with the influx of alkalis. Figures 1 and 3 are not very conclusive but they certainly do not indicate pure igneous or pure pelitic parentage to these granulites. The plot of Niggli mg against Cr and Ni is critical to discriminate whether the premetamorphic rock is a mixture of sediments of different compositions or a mixture of igneous and sedimentary series.

FIG. 4. Plot of Cr against mg for Madras and Niligiri leptynites. Note the positive correlation.

FIG. 5. Plot of Ni against mg for Madras and Niligiri leptynites. Note the positive correlation.

If the leptynites are formed by the metamorphism of the original pelites mixed with psammities or arkoses, the plot mg against Cr and Ni will give a negative correlation. On the contrary if they were original pelites into which were showered volcanic rocks, the plots would show a positive correlation (Leake, personal communication).

Nickel and chromium determined for six Nilgiri and Madras leptynites when plotted against Niggli mg show positive correlation (Figs. 4 and 5).

The authors therefore suggest that these leptynites have a hybrid premetamorphic origin. They were originally pelites which suffered igneous activity with the influx of alkalies and also alumina prior to metamorphism which resulted in the present garnetiferous quartzofeldspathic assemblage.

Thanks are due to Dr. Bernard E. Leake, University of Bristol, Bristol, U.K., for critical comments on the diagrams.

#### SEXUAL DIMORPHISM IN THE CLOACA OF *CALOTES VERSICOLOR* (DAUD)

WHILE working out the biology of *Calotes versicolor* we had opportunity of examining large number of lizards. Though the matured males are brilliantly coloured red yellow during breeding season the immature and young specimens give considerable difficulty in distinguishing sex externally as lizards look alike in their features. Smith (1935) states that there is still much to be learnt with regard to sexual dimorphism in lizards and it is important, therefore, to be able to sex a specimen accurately.

A closer observation of *C. versicolor* revealed that the cloacal structure showed sexual dimorphism. The dimorphic characters are diagrammatically represented in Fig. 1. A slit-like transverse

FIG. 1. Diagrammatic representation of cloaca showing dimorphic characters of *Calotes versicolor*.

cloacal aperture at the base of the tail occurs on the ventral surface. In natural state the cloacal aperture in male has two lips—an upper and a lower—covered with minute scales. When the tail is pulled down to expose internal cloacal aperture the exposed cloacal area gives a semicircular appearance with circular cloacal aperture lying in the centre of the circumference, while in female the cloaca has an external triangular flap covering the slit-like cloacal aperture and bears a nodular projection in the lower lip. The exposed cloacal area appears triangular and the internal cloacal aperture lies at the apex of the triangle. Blank (1967) described superficial sexual dimorphic characters in *Zonosaurus maximus* of Madagascar where in male there is an oval and in female a triangular large scale covering cloaca. These dimorphic characters are characteristic features of *Calotes* and can be reliably used for distinguishing the sexes of the lizards for using them for experimental purposes.

#### OCCURRENCE OF *OLPIDIUM BRASSICAE* IN INDIA

WORONIN (1878)<sup>2,5</sup>, while working with the club root disease of cabbage, observed a chytridiaceous fungus parasitizing the roots of crucifers and named it as *Chytridium brassicae* Woronin. The fungus was later transferred to the genus *Olpidium* (Braun) Rabenh. by Dangeard (1886)<sup>2,5</sup>. Relatively few

species of the genus *Olpidium* are reported parasitic in the roots of crop plants from the world<sup>1-5</sup>. Among these *Olpidium brassicae* has been known widely distributed and its parasitism reported in the seedling roots of several phanerogams.

During a survey of the root diseases of cruciferous crops, a chytridiaceous parasite was consistently encountered in the young roots of cabbage (*Brassica oleracea* L. var. *capitata*) and cauliflower (*Brassica oleracea* L. var. *botrytis*) seedlings in the low-lying, ill-drained heavy soil fields (pH 7 to 8.5) of Varanasi, U.P., during December and January. Diseased plants did not show any marked symptoms and incipiently infected seedlings developed normally. The infected roots looked apparently healthy, but in severe infections few rootlets and secondary roots showed pale reddish brown discoloration at the tips and slight unthriftness or sickness was the only sign of the disease noticed in the plants in the field and in pot cultures. Cabbage and cauliflower seeds sown in infested soil germinated normally and the seedlings developed with no external disease symptoms, but microscopic examination of the roots revealed abundant development of intracellular zoosporangia and resting spores of the pathogen.

The thalli developed in the first and third or fourth layers of the epiblema and were most abundant in the outermost layer. They were holocarpic, mostly cylindrical, thin-walled, with densely granular protoplasmic contents, variable in shape, measuring  $50-152.5 \times 14-23 \mu$  (Fig. 1). The thalli segmented into merons in a row, which became transformed into spherical to ellipsoidal, thin-walled zoosporangia singly or in a row in the cortical cells, being abundant in the outer layers (Fig. 2). Very few zoosporangia developed in the inner cell layers. They measured  $10-50.8 \times 10-35.6 \mu$ . Their walls were smooth and highly permeable to stains. Dense protoplasmic contents in maturing zoosporangia cleaved into uniflagellate zoospores, which escaped through the canal of the exit tube extending to the exterior or sometimes opening within the host tissues. The zoospores were numerous, spherical to pyriform,  $5.0-6.4 \mu$  in diam., bearing a single posterior flagellum,  $19.0-29.2 \mu$  in length.

Intracellular resting spores were formed abundantly in the outer cell layers often at the base of or within the root hairs and frequently in the deeper (3rd or 4th) layers (Fig. 3). They were thick-walled, hyaline and oval to globose in shape. The exospore was thick and warty. The endospore was thin and smooth. The resting spores measured  $9.2-38 \times 11.5-26.6 \mu$  (Fig. 4).

Morphology and development of sporangia, zoospores and resting sporangia of the pathogen indicated its identity to *Olpidium brassicae* (Wor.) Dangeard, to which it is referred. *Olpidium uredinis* (Lager.). Fischer and *O. indicum* Turner respectively parasitic in the urediospores of *Hemileia canthii* Berk. and Br. and in the filaments of *Oedogonium* sp. are the other species hitherto reported to occur in India<sup>6,7</sup>. The occurrence of *Olpidium brassicae* in the roots of cabbage and cauliflower constitutes the first record for India (IMI 181965, HClO 31782).

#### EMBRYO SAC DEVELOPMENT IN *SCILLA PERUVIANA* L.

THE two genera *Scilla* and *Endymion* were merged into a single genus *Scilla* for some time. Chouard (1931, 1934), however, restored *Endymion* to its former status so that the old genus *Scilla* of Linnaeus is now subdivided into *Urgenia* (Steinh.) Baker; *Scilla* (L.) Baker Emend. Chouard and *Endymion* (Dum.) Chouard. Two species of *Endymion*, *E. hispanicus* (= *Scilla hispanica*) and *E. non-scriptus* (= *Scilla non-scripta*) show a bisporic 8-nucleate embryo sac developed from the upper dyad cell, while the lower one develops upto the 4-nucleate stage finally forming the antipode. In the embryologically known species of *Scilla*, *S. indica* (Govindappa and Sheriff, 1951; Sulbha, 1954), *S. hyacinthina* (Sulbha, 1954), *S. autumnalis* (Battaglia, 1958) and *S. pratensis* (Battaglia and Feeley, 1959) and *Urgenia indica* (Capoor, 1937) a Polygonum type of embryo sac development has been reported. Battaglia and Feeley (1959) expressed the opinion that species of *Scilla* follow the Polygonum type of embryo sac development and those of *Endymion* conform to the special bisporic *Endymion* type. The present embryological study was endeavoured to trace the embryo sac development in *Scilla peruviana* L., a Mediterranean species, and to examine its bearing on its systematic position.

The tricarpellary ovary is superior, syncarpous and trilobular. Septal nectaries are present in the ovary and their pockets are lined with glandular cells (Fig. 11). A point of interest is the occurrence of abundant raphides in the crystal sacs of all the floral parts. The numerous anatropous,

bitegmal and crassinucellar ovules are collaterally borne on axile placentae (Fig. 11).

L.s. ovule showing the mature embryo sac, hypostase, enlarged nucellar epidermal cells and funicular obturator,  $\times 20$ . Fig. 9. L.s. part of ovule showing mature embryo sac, funicular obturator and the radially enlarged nucellar epidermal cells,  $\times 25$ . Fig. 10. Chalazal part of the ovule showing hypostase, hypertrophied antipodals and polar nuclei,  $\times 50$ . Fig. 11. C.s. Ovary. Note septal nectary,  $\times 3$ . (ant, antipodals; eg, egg apparatus; es, embryo sac; ii, inner integument; ob, funicular obturator; oi, outer integument; ov, ovules; hy, hypostase; p, polars; sn, septal nectary.)

A single hypodermal archesporial cell differentiates about the time the integumentary primordia begin to make their appearance. The archesporial cell cuts off a parietal cell (Fig. 1) which divides anticlinally and the derivatives thereupon divide

periodically. The megaspore mother cell undergoes the two meiotic divisions to procreate a tetrad of megaspores of which the chalazal only functions (Fig. 4). The tetrad of megaspores is either linear (Fig. 2) or T-shaped (Fig. 3). The nucleus of the chalazal megaspore undergoes the three free nuclear divisions resulting in an 8-nucleate embryo sac (Figs. 5, 6, 7), while the three micropylar ones degenerate (Fig. 4). The embryo sac development, therefore, is of the Polygonum type.

During the development of the female gametophyte there is a considerable enlargement leading to the destruction and absorption of the cells of the nucellus all around excepting at narrower chalazal part of the embryo sac (Figs. 8, 9). The persisting nucellar epidermal cells enlarge radially and the cells become highly vacuolated. The mature embryo sac shows the 3-celled egg apparatus, the two polar nuclei, which fuse in the vicinity of the antipodal cells resulting in the secondary nucleus, and the three antipodal cells which become hypertrophied and occupy the narrow chalazal part of the embryo sac (Figs. 8, 9, 10). A hypostase is discernible at the organised embryo sac stage (Fig. 8). In some preparations one or two antipodal cells were found to degenerate (Figs. 8, 9).

About the time the embryo sac matures a funicular obturator was found to be differentiating (Figs. 8, 9), a feature which does not seem to have been recorded for embryologically known species of *Scilla*.

From the evidence so far available, it is obvious, that the type of embryo sac development seems to favour the treatment of *Scilla* and *Endymion* as distinct genera.

## TOTAL SILICA AND BROWN SPOT DISEASE DEVELOPMENT OF RICE UNDER VARYING LEVELS OF NITROGEN

PRESENCE of silica in increased quantity in the leaves of wheat and rice plants conferred resistance to powdery mildew, blast and brown spot disease<sup>1,2</sup>. No data are available on the susceptibility of the rice plants to brown spot disease incited by *Helminthosporium oryzae* Breda de-Haan (under different doses of nitrogenous fertilization) and their silicon status of the leaves. The present investigation deals with this aspect.

Rice seedlings were raised in plastic pots (30 cm diameter) filled with quartz sand nourished with Hoagland solution which was adjusted for the various levels of nitrogen. Nitrogen was applied in the form of ammonium sulphate. There were 7 treatments, i.e., 0–60 Kg N/ha at 10 Kg interval with 3 replications. Patnai-23 and latisail for winter and latisail and CB-1 were chosen for summer season. Thirty days, 75 days and 90 days old plants were considered for seedling, tillering and preflowering stages of growth. For inoculation, H 39 strain of *H. oryzae* having 7,000 viable conidia/ml water was sprayed mixing a few drops of trixon-x as adhesive. The pots were flooded with sterile distilled water and kept under incubation for 96 hours. Infection value was calculated by collecting 25 leaves for each grade after Padmanabhan<sup>4</sup>. The pots were stored in a cool, dark place for 24 hr before collecting leaf samples for total silica analysis; just after recording the infection values. Total silica was analysed by standard method<sup>5</sup>.

For finding out the correlation between incidence of brown spot and percentage of total silica in rice leaf blades, statistical analysis was worked out<sup>6</sup> and the correlation value  $r$  together with degrees of freedom are presented in Tables I and II. The percentage of total silica for summer rice varieties, i.e., Latisail and CB-1 (Figs. 1, 2 and 3) was negatively correlated with the brown spot disease development. Statistically significant relationships for autumn and winter rice varieties (Tables I and II) were obtained between the silicon status of the host plant and intensity of infection of brown spot disease incited by *H. oryzae*. Higher concentration of total silica was recorded at the post-tillering stage in all the seasons while the disease intensity was minimum and the lowest was noted at the seedling stage which were attended with highest infection values. Similar observations were recorded in all the seasons. Increased amount of silica was noted in the rice leaves grown in summer and lowest in winter season whereas autumn rice showed the intermediate reaction. An interesting

Correlation between total silica and infection value

|         |          |          |          |
|---------|----------|----------|----------|
| D.F.    | 12       | 12       | 12       |
| r value | -0.97*** | -0.95*** | -0.98*** |

result (Figs. 1, 2 and 3) was observed in case of different doses of nitrogen. i.e., higher percentage of total silica at 20–40 kg N/ha level in all the seasons and at all the stages of the growth period which was inversely correlated with brown spot disease development. With excess of nitrogen level, i.e., 50–60 kg N/ha the disease intensity also increased and the silicon status decreased and the same was true with deficient level of nitrogen, i.e., 0–10 kg N/ha. No remarkable difference could be observed between the varieties in a particular season. Tasugi and Yoshida<sup>7</sup> explained about decreased silicon uptake of graminaceous plants

under excess nitrogen nutrition. But the present investigation could not offer any explanation about the decreased silicon content in rice leaves under deficient nitrogen level.

FIG. 1. Relationship of total silica to the incidence of brown spot disease of summer rice at 0–60 Kg N/ha level at seedling stage  $V_1$  = Latisail;  $V_2$  = CB-1.

FIG. 2. Relationship of total silica to the incidence of brown spot disease of summer rice at 0–60 Kg N/ha level at tillering stage.  $V_1$  = Latisail,  $V_2$  = CB-1.

FIG. 3. Relationship of total silica to the incidence of brown spot disease of summer rice at 0–60 Kg N/ha level at pre-flowering stage  $V_1$  = Latisail,  $V_2$  = CB-1.

Thus it may be concluded that silicon content of rice leaves and brown spot disease incidence are negatively correlated. Lower amount of silica in rice leaves stand for susceptibility to brown spot disease. Balanced nitrogen nutrition might be an important criterion for increasing the silicon status of rice leaves and making the rice crops less susceptible to brown spot disease.

**MERREMIA PELTATA (LINN.) MERR. (CONVOLVULACEAE)—A NEW RECORD TO INDIAN FLORA FROM GREAT NICOBAR ISLAND**

DURING a Joint Scientific Expedition to the Great Nicobar Island in 1966, an interesting member of Convolvulaceae was collected which on critical studies turned out to be *Merremia peltata* (Linn.) Merr., a species hitherto unrecorded from India. The plant is distributed in Malesia, Philippines, New Guinea, Madagascar, Mascarenes, Sechelles, Tropical Australia and Polynesia. The occurrence of this taxon in Great Nicobar Island is therefore not only a new record for India but represents an extension of its range of distribution up to the Nicobar Island. A detailed description of the taxon with an illustration is presented in this paper.

FIG. 1. *Merremia peltata* (Linn.) Merr. A branch with flowers.

*Merremia peltata* (Linn.) Merr. Interpr. Rumph., *Herb. Amb.* 441, 1917; Ooststr. in *Blumea* 3: 352, 1939, et van Steenis in *Fl. Buitenz.* 127, 1895; Ridley, *Fl. Mal.* 2: 458, 1923.

Twining. Leaves ovate-cordate to semi-orbicular 12–14 × 11.5–14.0 cm, alternate, long petiolate, distinctly peltate, entire, shortly apiculate at apex, glabrous; veins 8–9 pairs, reddish on the abaxial

side, radiating; petiole 7–12 cm long, glabrous. Flowers 2–4 in axillary cymes, yellow, 6–7 cm long; bracteate, bracteolate; pedicel 1.0–1.8 cm long. Sepals 5, free, coriaceous, 1.5–2.0 × 1.0–1.2 cm, greenish, imbricate, glabrous. Petals 5, united, bright yellow, glabrous; corolla tube funnel-shaped, 5 × 4 cm. Stamens 5, epipetalous; filaments dilated, hairy at base; anthers spirally twisted, hairy. Carpels 2, united, glabrous. Capsules subglobose, 4-loculed, 4-valved; seed 4, densely brown tomentose.

*Specimen examined*: Galathea river bank, Great Nicobar Island, 24–3–1966—*Thothathri and Banerjee* 11497 (CAL). A handsome twiner growing along river beds.

*Distribution*: Malesia, Philippines, New Guinea, Madagascar, Mascarenes, Sechelles and Tropical Australia.

**INVESTIGATIONS ON A MOSAIC DISEASE OF CAPE GOOSEBERRY**

CAPE gooseberry (*Physalis peruviana* L.) is one of the commercially grown fruit crops in some parts of India. During 1973, a mosaic disease was observed on *Physalis peruviana* in the germplasm collection of *Physalis* spp. at the Indian Institute of Horticultural Research, Hessaraghatta. The characteristic feature of the disease is severe mosaic mottling of the leaves. The leaves are reduced in size and very often exhibited symptoms of malformation and distortion (Fig. 1). The affected plants are stunted in growth. The number of flowers and fruits per plant was found to be less when compared to healthy plants. Investigations were therefore undertaken to identify the causal virus and the results obtained are presented in this communication.

Under artificial inoculation, the virus was readily transmissible by sap to the herbaceous hosts but restricted in its host range to the plants belonging to families Amarantaceae, Chenopodiaceae and Solanaceae. It produced mosaic mottling symptoms on *Nicotiana debnyii* L., *N. plumbaginifolia* L., *N. rustica* L., *Physalis angulata* L., *P. ixocarpa* Brot., *P. minima*, *P. peruviana* L., *P. floridana* Rydb., *Nicandra physaloides* (L.) Pers., and *Petunia hybrida* Vilm. Chlorotic local lesions were observed on *N. tabacum* L. var. Xanthi and on *Chenopodium quinoa* Willd. Necrotic local lesions followed by systemic necrosis was observed on *N. tabacum* L. var. W.B., while necrotic local lesions alone were produced on inoculated leaves of *Chenopodium amaranticolor*

Coste and Reyn., *C. album* L., *C. ambrosioides* L.,  
*C. murale* L. and *Gomphrena globosa* L.

FIG. 1. Gooseberry leaf showing mosaic and distortion symptoms.

Out of four species of aphids tested, viz., *Myzus persicae* Sulz., *Aphis gossypii* Glov., *A. craccivora* Koch., and *Macrosiphum sonchi* L., only *M. persicae* transmitted the virus successfully. The aphids were given one hour pre-acquisition fasting and 15 minutes of acquisition feeding on diseased plants. After acquisition feeding the viruliferous aphids were allowed to feed on the test plants overnight and then they were killed by 0.02% parathion spray.

The gooseberry mosaic virus (GMV) inoculum (sap) could tolerate heating at 55° C. for 10 minutes, but not at 60° C. The virus was infective at a dilution of 1 : 1,000 but not at 1 : 10,000. The longevity *in vitro* of the virus in crude sap was found to be 4 days at room temperature (28–30° C) but it increased up to 10 days when the crude sap was stored at 5° C.

The virus under study was tested with different antisera, viz., Cucumber mosaic virus (CMV), Tobacco ring spot virus (TRSV), Tobacco etch virus (TEV), Potato virus Y (PVY), Potato virus X (PVX), Tobacco mosaic virus (TMV) and egg plant mosaic virus (EMV). However, no positive reaction was observed with any one of the antisera tested indicating that it is not related to them.

Capoor and Sharma (1965)<sup>1</sup> reported a mosaic disease of Cape gooseberry caused by TMV. The virus under the present study did not produce local lesions on *N. glauca* and it also showed negative reaction with TMV antisera. Therefore it cannot be TMV or its strains. Since the present virus did not induce any symptoms on any of the cucurbitaceous hosts, the possible relationships with CMV has been eliminated. This was also confirmed by serological tests. Chamberlain (1939)<sup>2</sup>, and Nariani and Sharma (1971)<sup>3</sup> reported a mosaic disease of Cape gooseberry caused by CMV (*Cucumis virus 1*). Moline and Fries (1972)<sup>4</sup> isolated a virus from *Physalis* species which was serologically related to Belladonna mottle virus (BMV) but the virus, reported herein, does not resemble in its physical properties and host range with BMV. Horvath (1970)<sup>5</sup> reported *P. peruviana* as a symptomless carrier of potato viruses X and Y. Based on the physical properties, host range, vector transmission and serological tests, the virus under study has tentatively been identified as a new virus causing mosaic disease of Cape gooseberry in India.

The authors are highly grateful to Dr. G. S. Randhawa for providing facilities and encouragement. Thanks are also due to Dr. C. P. A. Iyer and to Mr. M. D. Subramaniam, for supplying seeds of different *Physalis* species.

#### **BALANOPHORA ABBREVIATA BLUME IN KARNATAKA**

THE curious root parasite *Balanophora abbreviata*, Balanophoraceae, was first collected in Java and described by Blume<sup>1</sup> in 1827. It has been subsequently recorded in Africa, Madagascar, Indo-China, Malaysia and the Pacific Islands. There is no mention of this species in any of the Indian Floras.

The authors have collected this taxon on the eastern bank of the Cauvery river near Ranganathittu, nine miles away from Mysore City, for the last five successive years, between July and October,

Since the species has a considerable range of distribution and recorded variability, an account of the observations made on the collected material is given below.

The fleshy achlorophyllous holoparasite is characterized by its distichous scale leaves and bisexual inflorescences with zygomorphic male flowers, located below the female part (Fig. 1). The plants

FIG. 1. *Balanophora abbreviata* Blume, adult plant with host roots.

grow in abundance, coming up like mushrooms, on the roots of *Acacia suma* Buch., Ham. and *Pithecolobium dulce* Benth. in sandy soil rich in humus well under shade. It is an annual appearing as small whitish or cream coloured underground nodules on newly produced young host roots soon after the first showers of the Southwest Monsoon. The nodules gradually develop into larger many-lobed tubers. The surface of the tuber is finely granular either with or without stellate warts. From each lobe bursts open a monoecious flowering scape bearing 4-6 distichous scale leaves, 20-40 almost sessile male flowers and innumerable female flowers. The bracts of the male flowers are small and needle-like when present. The tepals are usually four in number. The synandrium is laterally extended and consists of 15-25 anther loculi. The pollen grains are spherical and possess a finely spinulate exine bearing 8-12 circular pores. The female flowers are aggregated on an ovoid terminal capitulum. The spadiceles are long with an upper obconical part and a narrow lower region. The cuticular ridges of spadicele epidermis are conspicuous and lamellated. The archegonia-like pistils representing the female flowers are located both on the main

axis of the inflorescence and at the bases of the spadiceles.

During post-fertilization stages the male flowers wither, while the female flower bearing region enlarges considerably and acquires a dark gray colour. At the end of the growing season, by October, the entire plant body collapses and disappears leaving grain-like minute fruits, simulating the sand grains, to germinate and produce the next crop of parasite on young newly produced host rootlets in the succeeding season.

The taxon described by Haines<sup>2</sup> in his Botany of Bihar and Orissa as *B. polyandra*, the taxon recorded as *B. polyandra* near Visakhapatnam from Andhra Pradesh by Dutt<sup>3</sup> and the one created as a new species of *Acroblastum*, *A. ambavanense*, by Venkatareddi<sup>4</sup> from Poona District are essentially in agreement with the description of *Balanophora abbreviata* Blume (see Bertel Hansen<sup>5</sup>, 1972). *B. polyandra* Griff. is distinctly dioecious with actinomorphic male flowers and tri-porate pollen as against the monoecious *B. abbreviata* Blume in which the inflorescence is bisexual, and the male flowers are zygomorphic with polypantoporate pollen.

#### ON THE PREVALENCE OF ACTINOMYCETES IN THE RHIZOSPHERE OF THE MEDICINAL PLANT, *SOLANUM KHASIANUM*

ACTINOMYCETES have received little attention in relation to the rhizosphere phenomenon in crop plants<sup>1,2</sup> though emphasis has been on their antagonistic potentialities<sup>3-6</sup>. Actinomycetes were suppressed completely in the rhizosphere of medicinal plant, *Rauvolfia serpentina*<sup>7</sup>. In the present report, evidence is presented on the influence of the medicinal plant, *Solanum khasianum* Clarke on the nature of the actinomycetes in the rhizosphere.

The non-rhizosphere (control) and rhizosphere samples of 18 month old *S. khasianum* plants were collected from 0-3, 3-6 and 6-12 inch layers<sup>6</sup> and the actinomycete population was estimated employing Kuster's agar<sup>7</sup>. The morphological grouping of actinomycetes was established following moist

chamber slide culture method<sup>8</sup> and the antagonistic activity of the actinomycetes was assessed by the standard cross streak assay technique employing various bacterial and fungal test organisms.

Actinomycetes were recorded in larger numbers in the rhizosphere of *S. khasianum* and the rhizosphere effect (rhizosphere : soil ratio) varied from 3.9 to 7.1, the maximum being in the top layer (Table I) and these results are similar to earlier

TABLE I

*Actinomycete population in the non-rhizosphere and rhizosphere soils of S. khasianum from different depths*

| Depth<br>(inch) | Population in 10 <sup>4</sup> /g<br>oven dry soil |                        | R : S<br>ratio |
|-----------------|---|------------------------|----------------|
|                 | Rhizosphere<br>(R)                                | Non-rhizosphere<br>(S) |                |
| 0-3             | 43.3  | 6.1                    | 7.1            |
| 3-6             | 23.4  | 5.9                    | 4.0            |
| 6-12            | 21.0  | 5.4                    | 3.9            |

reports on the incidence of actinomycetes in the rhizosphere of perennial plants<sup>2,9</sup> and other crop plants<sup>3-6</sup>. The rhizosphere effect gradually decreased with the increase in depth and this is because of sudden decline in the actinomycete population in the second and third layers which is similar to the results from yellow birch seedlings<sup>9</sup>. The actinomycetes encountered in the rhizosphere soils belonged to genera *Streptomyces* (80.0%) and *Micromonospora* (20.0%) while *Nocardia* was absent whereas in the non-rhizosphere soils all the three genera were recorded. Among the *Streptomyces*, the series *Spira* was dominant followed by series *Rectus flexibilis* in the rhizosphere, while the series *Retinaculum apertum*, *Monoverticillus*, *Monoverticillus-spira* and *Biverticillus* were absent.

Actinomycetes with antibacterial activity alone were more predominant than those with antifungal and combined antibacterial and antifungal activity in both the rhizosphere and control soils (Table II). Similarly the abundance of antagonistic actinomycetes in the rhizosphere of *Citrus* spp. and other plant species<sup>1-5</sup> were reported earlier. Antagonistic actinomycetes were more in the top two layers while they were absent in third layer of the rhizosphere; the reasons for a specific suppression of antagonists in the deeper layer of the rhizosphere are not known. Majority of antagonists from the rhizosphere were specifically inhibitory to *S. aureus* and *P. solanacearum* and *S. cereviceae* whereas those from non-rhizosphere soil were inhibitory to *S. aureus*, *B. subtilis* and *X. malvacearum*.

TABLE II

*The incidence of antagonistic actinomycetes in the non-rhizosphere and rhizosphere soils of S. khasianum at different depths*

(Expressed as % of total actinomycetes population)

| Treatment              | Antagonistic actinomycetes |            |  |
|------------------------|----------------------------|------------|--|

# PATTERNS OF NODAL ANATOMY IN LOGANIACEAE

ONLY a few<sup>1,2</sup> investigations on the nodal anatomy of family Loganiaceae have appeared so far. The present communication is intended as a supplement to pre-existing literature incorporating the studies from the species belonging to mark 1, 2, 3 and 4 genera. viz., *Strychnos afzelii* Gilg., *S. congolana* Gilg., *S. dinklagei* Gilg., *S. malacoclados* Wright, *S. nux-vomica* L., *S. soubrensis* Hutch. et Dalz., *S. spinosa* Lam., *Nuxia floribunda* Benth., *Gomphostigma virgatum* (L.f.) Baill. and *Buddleia asiatica* Lour.

An internode reveals a complete vascular cylinder (Fig. 1). At the node, a single broad and arc-shaped trace is given off from the vascular cylinder and a gap is formed (Fig. 2). Minor variations are observed during the further course of trace which generally divides into three bundles (Fig. 3), almost of the same size on entering the petiole (e.g., *Strychnos spinosa*). In *S. afzelii* and *S. nux-vomica* the arc-shaped trace first divides itself into three (Fig. 4) middle one being heavier than the two small lateral ones. The latter divides into two each, at the base of the petiole thus supplying 5 bundles to the lamina (Fig. 5). In *S. soubrensis*, however, trace divides into a few, soon after it is given off (Fig. 6).

FIGS. 1-8. Fig. 1. Vascularity of the internode. Fig. 2. Arc-like leaf trace in *S. nux-vomica*. Fig. 3. Leaf trace dividing into 3 in *S. spinosa*. Figs. 4-5. Serial transsections of the node of *S. nux-vomica*. Fig. 6. T.S. node to show leaf trace dividing into many. Figs. 7-8. Serial transsections of the node of *G. virgatum*. (LT—leaf trace, L—lateral).

In *Gomphostigma virgatum* and *Buddleia asiatica* vascular cylinder (Fig. 7) gives off a single trace

which sends one lateral branch each on either side before entering the petiole. The lateral branches divide further to give rise to a branch, each supplying the stipular line before fading away (Fig. 8). In *B. asiatica* laterals are fully consumed.

The data accumulated so far brings forth three patterns of nodal anatomy: (1) multilacunar in *Fagraea* as recorded by Hasselberg<sup>2</sup>, (2) unilacunar single traced with laterals for stipular line, exemplified by *Buddleia asiatica* and (3) unilacunar with single broad, arc-shaped trace, e.g., *Strychnos spinosa*, etc.

The third of these categories needs further consideration since such a broad and arc-shaped trace represents several concrescent strands (Money, Bailey and Swamy, 1950)<sup>3</sup>. Accordingly the following three types indicating probable concrescent nature of arc-shaped trace are evident, (a) single trace dividing into several, (b) single trace dividing into five and (c) single trace dividing into three. The broad, arc-shaped trace, therefore, resulted from the fusion of several strands. Canright<sup>4</sup> considers such a trace as the most evolved among unilacunar types. It is possible that unilacunar condition with a broad arc-like trace represents the ultimate type of nodal pattern in Loganiaceae.

## ACTIVATED VERMICULITE AS AN INSECTICIDE

EARLIER investigations have indicated that clay minerals could be converted into highly insecticidal substances by activation treatment<sup>1-3</sup>. In the present study, acid and heat activation were carried out on some Indian vermiculites and their insecticidal properties are presented.

Four samples of vermiculite from different states were beneficiated by sedimentation and passed through 100 mesh (Tyler's Standard). Acid activation was carried out by autoclaving the samples with 10 N sulphuric acid at 15 lb/sq. inch pressure having clay acid ratio of 1:6 and washed free of sulphates with deionised water. After drying and pulverizing to 2 $\mu$  fraction, they were heated to 400° C in an electric muffle furnace for 3 hours<sup>1</sup>. The samples were tested for insecticidal activity using *Tribolium castaneum* (Herbst) adults as test insects and the bioassay was conducted in a chamber maintained at 85° F and 56% R.H. Mortality

count was taken after 7 hours exposure and 40 hours post-exposure period. Standard deviation for the replicates was calculated.

The study showed that heat activation alone did not produce any insecticidal activity but on acid heat activation the vermiculites from Karnataka and Bihar developed high insecticidal property (Table I). Vermiculite from Andhra Pradesh also

\* Per cent insect mortality. † Standard deviation. Degree of freedom 19.

gave good activity whereas pre-exfoliated vermiculite (package waste) on activation treatment showed lower insecticidal activity. It was also observed that samples which had acid solubility of more than 50% showed greater insecticidal property. The acid treatment produced more micro-capillaries on the particle surface and adsorbed lipids from the insect cuticle. The insect mortality was brought about by the resultant desiccation<sup>1,2</sup>.

Acute oral toxicity trials of vermiculite (2–8 g/kg) on albino rats were conducted to determine the mammalian safety. Even high level ingestion did not produce any toxic symptoms in rats for 48 hrs. The study also indicated that vermiculite is a safe and promising mineral for controlling stored-product insects.

I thank Dr. S. K. Majumder for his helpful suggestions and Dr. H. A. B. Parpia for his keen interest in this study.

### INFLUENCE OF ALDRIN ON RADIO-CARBON (<sup>14</sup>C-GLUCOSE) INCORPORATION BY TWO RHIZOBIUM SPECIES

APPLICATION of various insecticides to soil to control soil-borne insect pests is a common practice in modern agriculture. Some of these insecticides, especially chlorinated hydrocarbons, persist in soil for a long time. The effect of such persistent type of insecticides on the beneficial microorganisms in soil, such as *Rhizobium*, a symbiotic nitrogen fixing group of bacteria, is little understood. Oblisami *et al.*<sup>4</sup> reported that the insecticides endrin, carbofuran and disulfoton inhibited to varying degrees, the growth *in vitro* of *Rhizobium* from red gram; however, Balasubramanian<sup>1</sup> observed that lindane, upto 5 ppm concentration, did not affect the growth of *Rhizobium japonicum in vitro* but altered the carbon (glucose) metabolism of the organism. The effect of Aldrin (1, 2, 3, 4, 10, 10-hexachloro 1, 4, 4a, 5, 8, 8a-hexahydro-endo 1, 4-exo-5, 8-dimethanonaphthalene), a common soil applied insecticide, on the radiocarbon (<sup>14</sup>C-glucose) assimilation *in vitro* by two species of *Rhizobium* is reported in this communication.

*Rhizobium trifolii* from lucerne (*Medicago sativa* L.) and *Rhizobium* sp. from black gram (*Phaseolus mungo* var. *radiatus* Linn.) were grown in malt extract medium<sup>2</sup> for 48 hr. One ml of this culture was added to 99 ml of the medium contained in 250 ml Erlenmeyer flasks. Calculated quantities of Aldrin (prepared from 'Aldrex-20 EC' formulated by Shell chemicals) were added to each flask so as to obtain 1 ppm (normal level) and 2 ppm (two-fold level) final concentrations of the active ingredient. Duplicates were maintained under each treatment with appropriate controls. The flasks were then incubated on a gyratory shaker at 25°C. After 48 hr incubation, to each flask was added 1 ml of an aqueous solution of radio-active (<sup>14</sup>C) glucose (uniformly labelled) of specific activity 0.05 mc/ml (22 mc/mM of glucose) using an automatic micro-syringe and again incubated for 3 hr. The cells were then harvested by centrifuging at 27,000 g at 5°C for 10 min. with repeated washings with physiological saline.

One part of the cell pellet was taken in an aluminium planchet, demoi-stened under infra-red heat and the radioactivity monitored with a gas flow proportional counting system. Of the remaining portion of the cell mass, equal quantities (on wet weight basis) of cells of the two *Rhizobium* species were extracted with various solvents as described by Kamen<sup>3</sup> and the following cellular fractions were obtained in succession: (1) cold-TCA soluble fraction, (2) alcohol soluble fraction, (3) alcohol-ether soluble fraction, (4) hot-TCA

cpm: Counts per minute.

soluble fraction and (5) insoluble residue. One ml of each fraction was transferred to an aluminium planchet, evaporated to dryness under infra-red heat and the radioactivity monitored.

The per cent distribution of radioactivity in the cellular fractions of the two rhizobia is presented in Table I. The total radioactivity incorporated into the whole cells increased significantly with the insecticide treatment in both the rhizobial species indicating a general increase in the carbon ( $^{14}\text{C}$ -glucose) assimilation by the organism.

It is clear from the results that Aldrin treatment altered the  $^{14}\text{C}$ -glucose assimilation in different fractions of the cellular constituents of the two species of *Rhizobium* and the effect varied with the level of the insecticide. Balasubramanian<sup>1</sup> observed in *R. japonicum* that lindane, a gamma isomer of benzene hexachloride (BHC), altered the incorporation of radio-carbon ( $^{14}\text{C}$ -glucose) into the different constituents of the growing cells. The observed increase in the percentage incorporation of radio-carbon induced by the insecticide treatment, in the cold-TCA soluble fraction and the insoluble residue, presumably composed of polysaccharides and protein respectively, indicate increased synthesis of carbohydrates and proteins in the cells, at the cost of lipid synthesis (alcohol-ether soluble fraction), with no appreciable change in other cellular constituents, viz., alcohol soluble fraction (cell wall and cytoplasmic membranes) and hot-TCA soluble fraction (nucleic acids), in the two *Rhizobium* species. The exact mode of action of Aldrin on the carbon metabolism of *Rhizobium* spp. and the effect of such carbon assimilation process, as affected by the insecticide on the *Rhizobium*-legume symbiosis, are yet to be worked out.

#### EFFECT OF DIFFERENT CONCENTRATION OF ETHREL (2-CHLOROETHYL PHOSPHONIC ACID) ON THE PROPERTIES OF BANANA FRUITS DURING THE ARTIFICIAL RIPENING

THE plant growth activity of ethrel has been attributed primarily to its ability to release ethylene to plant tissues<sup>15-16</sup>. Burg<sup>3</sup> and others<sup>8-10</sup> have demonstrated the dramatic influence of ethylene on fruit ripening and maturity. However, a simple dipping procedure with ethrel would be of interest in many parts of the world. Postharvest dipping for 30 seconds to 3 minutes or spraying the fruit with ethrel has promoted ripening of bananas at 500 to 2,000 ppm<sup>5-14</sup>, pears at 250 to 1,000 ppm<sup>3-6, 11</sup>, pecans at 6,000 ppm<sup>9</sup> and mangoes at 100 to 10,000 ppm<sup>4</sup>. The present investigation is aimed at studying the effect of different concentrations of ethrel on fruit quality of "Maghraby" banana, during the artificial ripening.

*Materials and Methods.*—Eight mature bunches of "Maghraby" banana fruits (*Musa sapientum* var. Gros Michel), were used in this investigation,

representing four treatments of two bunches each. The banana bunches were sprayed with aqueous solutions of ethrel, at 0, 500, 1,000 or 2,000 ppm and were kept at room temperature (70–75° F). Determination of some physical and chemical characteristics of the fruits such as colour development, peelability, total soluble solids, total sugars, reducing sugars, non-reducing sugars were carried out at three day intervals. Extraction and determination of sugars were carried out according to the modified Schaffer-Hartmann<sup>13</sup> methods as described by Said<sup>12</sup>.

#### RESULTS AND DISCUSSION

1. *Colour Development.*—The colour development was estimated according to Fruit Dispatch Company Colour Chart<sup>7</sup>. The rate of colour development (Table I) was more rapid in fruits treated with 2,000 and 1,000 ppm than those treated with 500 and 0 ppm ethrel. These results are in agreement with those reported by Abou Aziz and Abd-El-Wahab<sup>1</sup>.

| 12                         | do.          | do.          | do.          | do.          |
| 15                         | Peeling      | ..           | ..           | ..           |
| 18                         | do.          | ..           | ..           | ..           |

2. *Peeling Condition.*—It seemed from Table II, that fruits were still hard to peel till the first sign of ripening was noticed. The time required to peel the banana fruits easily was shortened by 3–6 days depending on the concentration of ethrel. It is interesting to note that the colour test and peeling condition form a good criterion for evaluating the ripening of banana fruits.

3. *Total Soluble Solids.*—Data in Table III show a progressive and consistent increase in the total soluble solids during the ripening in the treated fruits. The increase of total soluble solids during ripening is due to the starch hydrolysis<sup>1,2</sup>.

4. *Total Sugars.*—The effect of different concentrations of ethrel on total sugars content of banana fruits is shown in Table IV. Total sugars reflect a gradual increase during the ripening of the banana fruits until the end of ripening stage. This was true in both treated and untreated fruits.

TABLE III

*Effect of different concentrations of Ethrel on the total soluble solids during the artificial ripening of banana fruits*

| Period of ripening (in days) | % total soluble solids |         |           |           |
|------------------------------|------------------------|---------|-----------|-----------|
|                              | Control                | 500 ppm | 1,000 ppm | 2,000 ppm |
| 0                            | 3.6                    | 3.6     | 3.6       | 3.6       |

T.S: total sugars,

R.S: reducing sugars,

Non-R.S: non-reducing sugars.

Maximum value of total sugars was high in the fruits treated with 2,000 ppm than those treated with 1,000 or 500 ppm of ethrel. It was also noticed that the reducing and the non-reducing sugars take a similar trend. Reducing sugars represent the major portion of the total sugars during the course of artificial ripening. This may be attributed to the early ripening process in the treated fruits. Fruits treated with 2,000 ppm of ethrel reflect a higher value of reducing and non-reducing sugars than those treated with 500 and 1,000 ppm.

## SHORT SCIENTIFIC NOTES

### Fertility in Relation to Different Haemoglobin Variants in Hariana Cows

Several attempts have been made to correlate haemoglobin types with fertility in sheep<sup>1,2</sup>. However, there appears no published information on the possible association between Hb types and fertility in Zebu cows. The present note reports the same. 645 Hariana cows of different Hb phenotypes were randomly bred to different bulls irrespective of their Hb types over a period of 4 years. Hb AA cows produced significantly more calves (62.6%) than either Hb AB (47.5%) or Hb BB (51.1%) animals. In addition, Hb AA animals appeared to calve at a significantly earlier age ( $1237 \pm 28$  days) than the Hb AB ( $1336 \pm 32$  days) and Hb BB ( $1340 \pm 25$  days) types. Calving interval was also slightly, though not significantly, shorter in Hb AA cows. Since Hb type in cattle is inherited as a simple Mendelian trait<sup>3</sup>, advantage can perhaps be taken of this apparent association between Hb types and reproductive efficiency for improving fertility in Zebu cattle through controlled breeding based on this physiological trait.

### Fertility in Relation to Red Cell Potassium Types in Murrah Buffaloes

A recent study<sup>1</sup> has indicated that the distribution of red cell potassium in buffaloes is genetically controlled. The possible association between red cell K<sup>+</sup> types and reproductive performance in Murrah buffaloes is reported here. The study was carried out with 256 buffalo cows and 11 buffalo bulls over a period of 3 years. Female fertility was nearly identical in HK (48.4%) and LK type (45.7%) of buffalo cows. In contrast, male fertility appeared to be related to red cell K<sup>+</sup> types, the trend being in favour of LK animals. Gross initial motility (LK — 2.02 and H.K. — 2.6), live sperm concentration  $\times 10^6/\text{ml}$  (LK — 1348, HK — 979) and fructolytic index (HK — 1.75; LK — 1.40) were significantly more in LK type than in HK type of bulls. Moreover, the LK bulls

appeared to be significantly more fertile (50.4%) than the HK bulls (33.8%). The no. of services per conception was not significantly different in the two groups (HK 1.86; LK 1.75). The present findings point to the practical possibility of selection of potentially more fertile young bulls at a very early age on the basis of red cell K<sup>+</sup> type.

### Additions to the Host Range of Bottle Gourd Mosaic Virus

A mosaic disease of bottle gourd (*Lagenaria leucantha*) is wide spread in Aligarh. Detailed studies with regard to the host range, symptomatology, thermal inactivation, longevity *in vitro*, dilution end point, transmission behaviour revealed that the virus is identical to the one described by Vasudeva *et al.*<sup>2</sup> and Shanker *et al.*<sup>1</sup>. In the host range studies, however, *Commelina nudiflora*, *Mukia maderaspatana* and *Salvia* sp. proved to be additional hosts of the virus. All these plants showed visible symptoms and the virus was recovered on back inoculation to *L. leucantha*. Though no visible symptoms were evoked on *Cucurbita pepo*, *Gomphrena globosa* and *Impatiens balsamina* yet on back inoculation virus was recovered and thus they served as symptomless carrier of the virus. *Datura stramonium* was described earlier (Vasudeva *et al.*<sup>2</sup>) as symptomless carrier, however, it was proved to be non-host in the present studies.

### Record of the Greenhouse Whitefly *Trialeurodes vaporariorum* (Westwood) on Tomato

The greenhouse whitefly *Trialeurodes vaporariorum* (Westwood) was first reported to occur in India by David<sup>1</sup> infesting potato (*Solanum tuberosum*) at Thummanatty (Nilgiris). Recently, the

insect was noticed for the first time to infest severely tomato (*Lycopersicon esculentum*) plants and to a mild extent French bean (*Glycine max*) at Kotagiri (Nilgiris).

The species being a plastic one exhibits conspicuous variation which can be correlated with the physical properties of the leaves it inhabits. The specimens collected agreed with the structural features of the pupal cases that occur on moderately hairy leaf, except for the difference in the length of the 8th abdominal setae which were about  $87\mu$  long as against 10 to  $20\mu$  in the normal form.

The occurrence of the whitefly at Thummanatty and Kotagiri indicates that the species is widely prevalent in the Nilgiris and a thorough search may add to the discovery of additional hosts.

#### Grafting Behaviour Between *Lycopersicon esculentum* L. Var. Marglobe and *Solanum* spp. (*Solanum torvum* and *S. melongena* L.)

Grafting has been an important method of overcoming incompatibility barriers in crosses between species of the genus and genera of the family. Hely *et al.* (1953)<sup>1</sup>, grafted *Trifolium repens* on to *T. ambiguum* and achieved good result. Later, Nirk (1959)<sup>2</sup> obtained eight self sterile interspecific hybrids by grafting prior to crossing, *L. esculentum* and *L. peruvianum*. In the present study, wedge grafting was used to make grafts between *Solanum* spp. and *L. esculentum*. *Solanum torvum* which is a perennial species with an elaborate root system and which is a hardy crop, was used as stock and *L. esculentum* was used as scion. The objects were to examine the possibilities of making *L. esculentum* perennial, increase its life span, make it drought and disease (wilt) resistant. Observations revealed that stock-scion establishment was early, remained for a longer period with profuse flowering in *S. melongena* and *L. esculentum* grafts compared to *S. torvum* and *L. esculentum*. In addition, the number of successful grafts were more in the former grafting than in the latter. But in both the cases the grafts could not be made to remain

perennial. Pollen studies in the grafted plants indicated no significant pollen sterility. A plausible explanation for this failure may be the inability of *L. esculentum* to maintain the seasonal hormonal balance like *S. torvum* which is perennial.

#### ANNOUNCEMENTS

Nominations for Science Academy Medals for young Scientists for 1975 are invited. The last date is February 28, 1975. For details please apply to the Executive Secretary, Indian National Science Academy, New Delhi-1.

#### Award of Research Degree

Karnatak University, Dharwar, has awarded the Ph.D. degree in Chemistry to Mrs. Renuka Rani Nagendrappa for her thesis entitled "Some Studies of Donor Acceptor Complexes"; Ph.D. degree in Zoology to (Miss) K. Dakshayani for her thesis entitled "Influence of Nutrition, Temperature, Groupsize and Photoperiod on Nymphal Growth and Development of the Cricket, *Pleaeiogryllus guttiventris* Walker"; Ph.D. degree in Chemistry to Shri Mohan Ramanath Shanbhag for his thesis entitled "Studies in Fatty Acids"; Ph.D. degree in Zoology to Shri Srinivas Kishanrao, Saidapur, for his thesis entitled "Studies on the Gonads of *Rana gyanophlyctis*, *Rana tigrina* and *Bufo melanostictus* (Amphibia) with reference to steroidogenic cellular sites"; Ph.D. degree in Geology to Shri Veerappa Chanbasappa Chavadi for his thesis entitled "Geology of the mafic and the other associated rocks of Savantavadi area, Ratnagiri District, Maharashtra State".

Osmania University, Hyderabad, has awarded the Ph.D. degree in Physics to Shri Sarada Prasad Mohanty for his thesis entitled "Theory of Orbital Susceptibility of Metals with complicated crystal structures"; Ph.D. degree in Physics to Shri S. P. Mallikarjun Rao for his thesis entitled "Ultrasonic Studies in Liquids by Reverberation Technique"; Ph.D. degree in Chemistry to Shri P. K. Sai Prakash for his thesis entitled "A Kinetic Study of some Aspects of Oxidation of Organic Substrates".

## INFORMATION TO CONTRIBUTORS

CURRENT SCIENCE is the Premier Science Fortnightly of India published by the Current Science Association, Bangalore and issued on the 5th and 20th of each month. All material intended for publication in CURRENT SCIENCE and books for review should be addressed to the Editor, *Current Science*, Raman Research Institute, Bangalore-560006.

The following types of Scientific Communications will be considered for publication :

- (i) Review articles on topics of major current interest not exceeding 4,000 words;
- (ii) Original Research Papers—not exceeding 2,000 words;
- (iii) Letters : These are brief reports of research of unusual and wide interest—they should not exceed 700 words in general;
- (iv) Short Scientific Notes—not exceeding 250 words.

Articles and papers should include a short abstract at the beginning.

References are indicated by superscripts in the text. The style of references should be

*Journal* : The names of the authors, the journal, year, volume and page.

*Book* : Authors names, the title of the book, name and location of the publishers, year and page.

"Personal Communications" and "Unpublished Work" do not go into references and should be incorporated in the text. Acknowledgements should be brief.

Statements that the work is contribution No..... of the Institute, declarations that the Director has authorised publications, etc., are not printed.

"Series" papers are discouraged.

Manuscripts, to be submitted in duplicate, should be typewritten in double space on one side of the paper, carefully revised and in final form for printing. Illustrations should be minimum in number, drawn in black and white with Indian ink on bristol board. Figures are usually reduced to one column width, and the originals should be about twice their final size.

No reprints are supplied gratis, but can be had on request at cost per V.P.P.

Business correspondence, remittances, subscriptions, advertisements, reprints, exchange journals, etc., should be addressed to the Manager, Current Science Association, Raman Research Institute, Bangalore-560006.

---

### Subscription Rates :

Institutions : India Rs. 84·00; Foreign Rs. 150·00; S 20·00 or £ 8·00.

Individuals : India Rs. 24·00; Foreign £ 3·50; \$ 8·00.

# CURRENT SCIENCE

*Fortnightly Journal of Research*

Issued on the 5th and 20th of each month

## IMPORTANT NOTICE TO SUBSCRIBERS OF THE JOURNAL

As you are aware CURRENT SCIENCE has been coming out regularly on the due dates as above with the kind co-operation of you all.

On account of the sharp increase in the cost of quality paper used for the Journal, increase in rates of block making materials, increase in postal rates and the increase in the establishment charges it has become impossible for the Association to issue the Journal, unless the subscription rates are put up.

The Working Committee of the Association has reluctantly decided at its last meeting, to enhance the subscription of CURRENT SCIENCE with effect from 1st January 1975 for institutions :

India Rs. 84/- Foreign Rs. 150.00 \$ 20.00 or £ 8.0.0

The subscription rates for individual subscribers however will remain the same as now.

The continued co-operation of our subscribers is requested.

## ABSTRACT

A normal coordinate analysis of sulphamide  $\text{SO}_2(\text{NH}_2)_2$  molecule is carried out using the 'characteristic set of valence coordinates' introduced by Herranz and Castano<sup>1</sup> and a set of potential energy constants is reported. Mean vibrational amplitudes, coriolis constants and thermodynamic quantities for a harmonic oscillator approximation, at different temperatures are also evaluated.

## INTRODUCTION

THE study of sulphamide is of general interest because of its marked acid properties and its ability to form salts of the type  $\text{SO}_2(\text{NHAg})_2$ . The exact nature of the force field of a molecule cannot be determined unambiguously from the vibrational frequencies alone. To fix the force fields completely, additional data like mean vibrational amplitudes, coriolis constants and thermodynamic properties are often necessary. However, approximate force fields can be determined using the kinematic method suggested by Herranz and Castano<sup>1</sup>. The present paper deals with the analysis of molecular force fields of the sulphamide molecule using the above method.

## 1. POTENTIAL ENERGY CONSTANTS

The molecule sulphamide belongs to  $C_{2v}$  point group nearly in agreement with X-ray results<sup>2</sup> and with the fundamental vibrational frequencies<sup>2</sup> falling under the irreducible representation  $\tau = 4a_1 + 1a_2 + 2b_1 + 2b_2$ . From the vibrational frequencies<sup>2</sup> and structural parameters<sup>3</sup> of this molecule, the symmetry coordinates and the corresponding inverse kinetic energy G matrix elements were constructed. The potential energy F matrix elements were obtained by Herranz and Castano method<sup>1</sup>.

$$L^{-1} = BM^{\dagger}B^*$$

where B is the orthogonal matrix which diagonalises G. M is a diagonal matrix whose elements are the reciprocals of the eigenvalues of G. The asterisk refers to the transpose. The symmetry force constant matrix is given by

$$F = L^{-1*} \Omega L^{-1}$$

where  $\Omega$  is a diagonal matrix with

$$\Omega_k = 4\pi^2 c^2 \gamma_k^2$$

$\gamma_k$  is the  $k$ th frequency ( $\text{cm}^{-1}$ ) and  $c$  is the velocity of light ( $\text{cm/sec}$ ). The symmetry coordinates in the present work are essentially the same as those of Ramaswamy and Jayaraman<sup>4</sup> where the constants  $a$ ,  $b$ ,  $c$  and  $d$  have the

following values :  $a = 0.852099$ ,  $b = 0.977023$ ,  $c = 0.420161$ , and  $d = 1$ .

Also  $D = S - O$ ,  $d = S - (\text{NH}_2)$ ,  $a = \text{O}\hat{S}\text{O}$   
 $\beta = (\text{NH}_2) - \hat{S} - (\text{NH}_2)$  and  $\gamma = (\text{NH}_2) - \hat{S} - O$ .

The valence force constants thus evaluated are presented in Table I.

TABLE I

Valence force constants of sulphamide molecule

## 2. MEAN AMPLITUDE OF VIBRATIONS

The important vibrational mean amplitudes of different bonds were calculated by the method of Cyvin<sup>5</sup> and the nonbonded ones by the method of Ramaswamy *et al.*<sup>6</sup> and are presented in Table II.

TABLE II

#### 4. THERMODYNAMIC PROPERTIES OF SULPHAMIDE

A set of thermodynamic quantities is also calculated and presented in Table IV.

Principal moments of inertia calculated are

$$I_{xx} = 97.4299 \text{ a.m.u.}\text{\AA}^2, \quad I_{yy} = 87.0582 \text{ a.m.u.}\text{\AA}^2, \\ I_{zz} = 102.2358 \text{ a.m.u.}\text{\AA}^2.$$

#### RESULTS AND DISCUSSION

In these calculations, the approximation that the  $(\text{NH}_2)$  group is a point mass, has been made. The mean amplitude value for nonbonded distance  $\text{O} \cdots \text{O}$  (0.05548 Å) agrees favourably with others<sup>8,9</sup> for similar types of molecules. The reliability of the  $\zeta$  (zeta) of Table III is confirmed since they obey the following sum rules.

$$(\zeta_{18}^x)^2 + (\zeta_{28}^x)^2 + (\zeta_{38}^x)^2 + (\zeta_{48}^x)^2 = 1 \\ (\zeta_{19}^x)^2 + (\zeta_{29}^x)^2 + (\zeta_{39}^x)^2 + (\zeta_{49}^x)^2 = 1 \\ (\zeta_{16}^y)^2 + (\zeta_{26}^y)^2 + (\zeta_{36}^y)^2 + (\zeta_{46}^y)^2 = 1 \\ (\zeta_{15}^z)^2 + (\zeta_{25}^z)^2 + (\zeta_{35}^z)^2 + (\zeta_{45}^z)^2 = 1$$

At present no experimental data are available to check the calculations of coriolis constants, mean amplitudes and thermodynamic properties reported in this paper. From the bond order calculation<sup>10</sup> [S-O (2.2), S-N (1.7)] supporting the resonance structure, the valence bond structure may be written

In each  $>\text{N-H}$  bond there may be resonance between the covalent and the ionic  $>\text{N}^+\text{H}^-$  states and the formation of negative charge on the nitrogen atom increases the stability of the molecule in view of the gain of electrostatic energy in the S-N bond. Thus the contribution of the structure

may be large in view of the increased stability produced by the alternative positive and negative charges. The marked acid properties of sulphamide and its ability to form salts of the type  $\text{SO}_2(\text{NHAg})_2$  may be in agreement with this structure.

The authors express their thanks to Dr. K. N. Kuchela and to Prof. M. A. Venkatachar for their interest in this work.

## NEUTRAL COMPONENTS OF *THESPEsia POPULNEA* FLOWERS

T. R. SESHADRI AND N. N. SHARMA

Department of Chemistry, University of Delhi, Delhi 110007

### ABSTRACT

The flowers of *Thespesia populnea* have been found to contain nonacosane, lupenone, myricyl alcohol, lupeol,  $\beta$ -sitosterol and  $\beta$ -sitosterol- $\beta$ -D-glucoside.

THE flowers of *Thespesia populnea* have been investigated a number of times in the past, with reference to the polyphenolic components present<sup>1-3</sup>. When the material is extracted in succession with petroleum ether (60–80°), acetone and alcohol, the flavonoids as aglycones and glycosides are found largely in the alcoholic extract<sup>4</sup>. The petroleum ether extract has yielded (+) gossypol as the main component<sup>5</sup>. The present note gives particulars of neutral components now isolated.

The flowers of *Thespesia populnea* (3 kg) were exhaustively extracted with petroleum ether (60–80°) and the extract deposited the yellow pigment (+) gossypol, reported earlier by Datta *et al.*<sup>5</sup>. The petroleum ether was completely removed and the residue taken up in ether. It was extracted with sodium hydroxide. Acidification of the alkaline extract gave a little more of (+) gossypol. On evaporation of the remaining ether extract a dark coloured semi-solid was obtained. It was adsorbed on silica gel and chromatographed on a column of the same whereby the following compounds were obtained.

Compound A, eluted with petroleum ether, had m.p. 64–65° (300 mg, from acetone). Its I.R. spectrum showed that it was aliphatic in nature. It did not answer Liebermann-Burchard test and moved to solvent front on TLC in *n*-hexane. Its mass-spectrum showed a very weak parent peak at *m/e* 408 and showed a cluster of peaks 14 units ( $-\text{CH}_2$ ) apart. The largest peak in each cluster represented  $\text{C}_n\text{H}_{2n+1}$  fragment which was accompanied by  $\text{C}_n\text{H}_{2n}$  and  $\text{C}_n\text{H}_{2n-1}$  peaks. Very

intense peaks were for C-4 and C-5 units and the fragment intensity decreased in a smooth curve up to  $(\text{M}^+-\text{C}_2\text{H}_5)$ . The  $(\text{M}^+-\text{CH}_3)$  peak was very small. The compound was identified as nonacosane.

Compound B, eluted with petroleum ether-benzene (1 : 1), had m.p. 168–170° (from acetone, 40 mg),  $[\alpha]_D - 40^\circ$ ;  $\nu_{\max}$  1725  $\text{cm}^{-1}$  (C=O) and gave a phenyl hydrazone, m.p. above 300°. Liebermann-Burchard test was positive. The compound was identified as lupenone.

Compound C, eluted with benzene, had m.p. 80° (from acetone, 200 mg),  $\nu_{\max}$  3500  $\text{cm}^{-1}$  (OH) and gave an acetate, m.p. 67–69°. The mass-spectrum of the acetate showed the parent peak at *m/e* 480 and the base peak at 421, confirming the presence of the acetate group ( $\text{M}^+-59$ ). It also showed a cluster of peaks 14 units ( $-\text{CH}_2$ ) apart. Very intense peaks were for C-6, C-7 and C-8 units. The compound was identified as myricyl alcohol.

Compound D, eluted with benzene : chloroform (3 : 1), had m.p. 218° (from methanol, 80 mg),  $[\alpha]_D + 20^\circ$ ;  $\nu_{\max}$  3500  $\text{cm}^{-1}$  (OH). It formed an acetate, m.p. 215°.  $[\alpha]_D + 50^\circ$ . Liebermann-Burchard test was positive. The compound was identified as lupeol.

Compound E, eluted with benzene : chloroform (1 : 3), had m.p. 136–137° (from methanol, 200 mg),  $[\alpha]_D - 40^\circ$ ;  $\nu_{\max}$  3500  $\text{cm}^{-1}$  (OH) and gave an acetate, m.p. 125–126° (from methanol),  $[\alpha]_D - 35^\circ$ . Liebermann-Burchard and TNM tests were positive. The compound was identified as  $\beta$ -sitosterol.

Compound F, eluted with chloroform : methanol (95 : 5), did not melt up to 300° and was not

easily soluble in ordinary solvents (50 mg).  $[\alpha]_D^{25} - 50^\circ$  (pyridine). Acid hydrolysis gave  $\beta$ -sitosterol and D-glucose. Permethylation of compound F by Hakomori's method and subsequent hydrolysis by Kiliani's reagent (HCl : AcOH :  $H_2O$  : 1 : 3 : 5 : 5 : 5) gave  $\beta$ -sitosterol and 2, 3, 4, 6-tetra-O-methyl D-glucose. Enzymatic hydrolysis with emulsin showed  $\beta$ -linkage. The compound was identified as  $\beta$ -sitosterol- $\beta$ -D-glucoside.

## METABOLISM IN *MYTILOPSIS SALLEI* (RECLUZ) (PELECYPODA): INFLUENCE OF TEMPERATURE

K. MANGAPATHI RAO,\* P. RAMACHANDRA RAJU,\* S. S. GANTI\* AND  
N. KALYANASUNDARAM

*Naval Science and Technological Laboratory, Visakhapatnam-3*

THE inter-tidal zone experiences to a great degree the vicissitudes of terrestrial climate and at low tide zone the marine animals are subjected to a wide range of temperature fluctuations. Ghiretti<sup>1</sup> observed that the metabolic rate is generally related to temperature in molluscs as in other poikilotherms. The effect of temperature on the respiration of many molluscs has been studied earlier<sup>2-8</sup>. However, studies on the effect of temperature on bivalves appear to have received limited attention<sup>6-9</sup>.

*Mytilopsis sallei* (Recluz) is a central American species which has migrated to Indian waters in recent years and has shown extensive propagation in local waters<sup>10</sup>. The animal has been found to withstand variations in salinities ranging from fresh water to 50‰ as determined earlier<sup>11</sup>. In the present studies, investigations were undertaken to examine the influence of temperature ranging from 5°C to 40°C on the metabolism of the bivalve *M. sallei*.

### MATERIAL AND METHODS

The experimental animals were collected from test panels exposed at the local harbour and were allowed to acclimatise overnight in the laboratory. Healthy animals of various size groups were then selected and taken in respiratory chambers individually<sup>12</sup>. The experiments on the respiration of the animals were conducted at various controlled temperatures ranging from 5°C to 40°C at every five degree interval. It was ensured that the sea-water temperature in the experimental jars was brought to the required level prior to the beginning of the experiment. The respiratory chambers containing individual animals were then flushed with nitrogen to remove any oxygen. A series of experiments were conducted at each temperature

and the minimal and maximal rates of respiration were determined. This was regarded as the index of active and standard rates of metabolism<sup>13</sup>. Fresh lot of animals previously acclimatised in the laboratory were selected for each temperature.

### RESULTS

The metabolic rate was calculated from the following formula<sup>14</sup>:

$$Y' = aX^{b'}$$

where  $Y'$  = the respiration rate ( $Y/X$ )

$X$  = the body weight

$a$  = constant

and  $b'$  = the specific exponent of weight ( $b-1$ ).

A calculated regression line of the metabolic rates (both standard and active) in relation to body size has been drawn for each temperature level on a double log scale as shown in Fig. 1. The effect of temperature on animals of 100 mg body weight has been reconstructed from Fig. 1 and drawn on a semilogarithmic scale (Fig. 2). On the basis of standard and active metabolic rates determined earlier, scope of activity at different temperatures examined has also been determined (Fig. 3).

It may be observed from the results (Fig. 1) that the value of  $b$  varies with temperature in the mussel *M. sallei*. The slope of regression correspondingly varied with temperature both for active and standard metabolic rate. The standard rate of metabolism appeared to show a general trend, increasing with increase in temperature. The active rate, on the other hand, showed a variable response to temperature and apparently no general pattern could be observed. The active rate was generally higher at 5°C, 15°C and 30°C. The active rate of metabolism, however, decreased beyond 30°C. The scope of activity as shown in Fig. 3 indicates clearly that the maximum activity of these species is recorded at 15°C. Although another peak was

\* Present address: Naval Chemical and Metallurgical Laboratory, Naval Dockyard, Bombay 400001.

also obtained at 30° C. the scope here was much less than that of 15° C.

by temperature changes. The basal rate of metabolism, however, showed a trend towards an increase

FIG. 1. Active (A) and standard (S) metabolic rates of *Mytilopsis sallei* in relation to body size at different temperatures.

FIG. 2. The effect of temperature on the 100 mg size animal—reconstructed.

FIG. 3. Influence of temperature on the scope for activity.

#### DISCUSSION

It may be observed from the results that the metabolism in *M. sallei* remains generally unaffected

with increase in temperature. The active rate on the other hand showed fairly wide fluctuations at different temperature. Similar fluctuations in the active rate of metabolism have also been recorded earlier for *Mytilus edulis* and *Littorina littorea*<sup>9</sup>.

The effect of temperature on active and standard rates of respiration of a wide variety of inter-tidal invertebrates have been studied earlier<sup>13-15</sup> and extensively reviewed by Newell<sup>16</sup>. In many species the temperature affected the active rate of oxygen consumption to a much greater extent than the standard rate and the rate of active metabolism increased with increase in temperature upto a certain level<sup>18,17</sup>. Barcroft<sup>18</sup> and Bullock<sup>19</sup> on the other hand have demonstrated that the metabolism does not increase regularly with temperature. The scope of activity, being the difference between the active and standard rate, does not appear to follow any uniform pattern in the case of *M. sallei* and in fact is comparatively more at lower temperatures than at higher temperatures.

The significance of this temperature-independent metabolism has been discussed in detail by Barcroft<sup>18</sup>, Bullock<sup>19</sup>, Davies<sup>14</sup> and recently by Newell and Northcroft<sup>13</sup>. It is generally agreed that the relatively undisturbed metabolism over a range of temperatures would indicate an important homeostatic mechanism in a poikilotherm and that this would allow the rates of metabolic reactions to proceed at a relatively constant rate despite the fluctuations in environmental temperature in the intertidal zone.

The authors wish to acknowledge the encouragement given to this work by Captain P. R. Sen. I.N., Director and Sri. S. V. S. Rao, Deputy Director of this laboratory.

## EFFECT OF IONIZING RADIATION ON SEED GERMINATION OF *PASSIFLORA* SPECIES

S. G. TORNE AND (MISS) N. P. RAUT DESAI

*Department of Botany, S. P. Chowgule College, Margao, Goa*

THE recent popularity of the genus *Passiflora*, because of its edible species, has attracted the attention not only of taxonomists but also of cytogeneticists. Of the 400 known species of *Passiflora*, about 50 to 60 bear edible fruits. Probably all these are indigenous to the American tropics. In most areas of the tropical and subtropical world where passion fruit is grown, the species *P. edulis* Sims. (purple passion fruit) predominates. Purple passion fruit, because of its high fruit quality is by far more popular in Australia, New Zealand, Brazil and S. Africa. In India it is known only in some parts. Besides the juice, purple passion fruit also contains vitamin A and niacin<sup>1</sup>. Commercial production of this fruit has limitations because of its susceptibility to common pests and diseases and intolerance to cold.

Seed germination percentage has been found to be very poor in *P. edulis* and to a certain extent in *P. foetida* Linn. Ionizing radiations could be of great importance as a means for removing the dormancy of the plant material, increasing the germination and germination energy of seeds, tubers and roots.

Seeds of *P. edulis* were obtained from Sims Park, Nilgiris and those of *P. foetida* were obtained from Agriculture and Fisheries Department, Kowloon, Hong Kong. Seeds of both the species were surface sterilized before they were dispatched to BARC, Trombay, for irradiation. The irradiation treatment consisted of 12 levels of gamma rays ranging

from 1 kr to 30 kr with 150 seed sample used per dose. The entire experiment was repeated twice and the mean was tabulated and given in Table I.

TABLE I  
Germination and survival percentage of *P. edulis* and *P. foetida* seeds irradiated with gamma rays.  
Data taken after 30 days of survival

| Dose    | <i>P. edulis</i> |            | <i>P. foetida</i> |            |
|---------|------------------|------------|-------------------|------------|
|         | Germination %    | Survival % | Germination %     | Survival % |
| Control | 33.4             | 33.5       | 38.7              | 67.3       |
| 1 kr    | 87.6             | 90.4       | 80.5              | 94.6       |
| 1.5 kr  | 82.3             | 100.0      | 84.8              | 92.3       |
| 2 kr    | 88.7             | 92.4       | 81.4              | 93.4       |
| 2.5 kr  | 80.7             | 83.7       | 94.5              | 91.7       |
| 5 kr    | 74.6             | 76.8       | 89.7              | 84.7       |
| 7.5 kr  | 68.3             | 61.3       | 84.5              | 82.3       |
| 10 kr   | 59.7             | 45.7       | 79.8              | 68.4       |
| 12.5 kr | 48.3             | 43.7       | 69.4              | 58.7       |
| 15 kr   | 41.5             | 40.2       | 59.8              | 51.3       |
| 20 kr   | 18.4             | 14.8       | 33.6              | 27.8       |
| 25 kr   | 06.7             | 04.5       | 27.6              | 18.5       |
| 30 kr   | 00.0             | 00.0       | 00.0              | 00.0       |

The irradiated seeds were sown within 24 hours, in pots together with the control seeds. Survival percentage for each dose was determined.

Table I indicates that the percentage of seed germination in both the species was found to have increased at lower doses over those of control but the survival percentage of seedlings increased considerably at lower doses ranging from 1 kr to

5 kr in *P. edulis* and from 1 kr to 10 kr in *P. foetida*. After 15 kr there was observed a sudden drop in the germination as well as in the survival percentage in both the species. More or less similar type of results were obtained in *Lupinus luteus*, *Papaver somniferum*<sup>4</sup>; *Datura stramonium*<sup>5</sup>.

The seeds of both the species which were irradiated at lower doses were found to have germinated earlier than those of the control and of higher doses. The effect of ionizing radiation on the acceleration of seed germination was indicated very clearly. Between 1 kr to 2.5 kr, seeds germinated within 18 to 21 days while seeds of control *P. edulis* took 29 days for germination. While at 1 kr to 2 kr seeds of *P. foetida* germinated within 10 days but the germination was observed on 15th day in control seeds. Almost every investigator found that germination and germination energy of seeds increased after irradiation with small doses<sup>6,7</sup>.

FIG. 1. Relation of survival in the seeds of *P. edulis* exposed to different doses of gamma rays.

In Sweden and in U.S.A. plant breeders who use radiation are employing the so-called "critical dose" in which about 40% of the plants survive. According to Dubinin<sup>8</sup> a critical dose of radiation is the one in which an appreciable depression is observed in the development of plants, but at which, an adequate number of plants remains capable of producing seeds. Also there is a relation between the radiosensitivity, number of chromosomes in cells

and their size in different species of plants. Such a comparison was made by Sparrow<sup>9</sup>. It has been found that in general plants with a similar number of chromosomes have almost equal radiosensitivity. The radiosensitivity is being figured here in the term of critical dose. In the present investigation *P. edulis* which has  $2n = 18$  and with large chromosomes (range  $47.9 \mu - 13.19 \mu$ ), the critical dose is 14.5 kr (Fig. 1) while *P. foetida* with  $2n = 22$  and with comparatively smaller chromosomes (range  $28.42 \mu - 4.9 \mu$ ) has a critical dose as 18 kr (Fig. 2).

FIG. 2. Relation of survival in the seeds of *P. foetida* exposed to different doses of gamma rays.

The authors are very much thankful to the Industries Commissioner, SIRC, Government of Maharashtra, Bombay, for financial assistance.

## EXCLUSIVELY "RED" FLIGHT MUSCLE: METABOLIC SPECIALIZATION AND SPECIFIC FLIGHT PHYSIOLOGY

C. L. TALESARA AND P. KUMAR\*

*Muscle Physiology and Histochemistry Unit, Department of Zoology, University of Delhi, Delhi-110007, India*

### ABSTRACT

The main flight muscle of certain bats and finches is composed exclusively of red fibres. These fibres, unlike the fibres of most mixed muscles, possess distinct capacity for glycolytic (anaerobic) as well as lipoxidative (aerobic) types of metabolism. The metabolic quality of this highly active muscle seems to be related to its contractile physiology.

### INTRODUCTION

THE flight muscles of most birds and bats, unlike other vertebrate skeletal muscles, are adapted for contractions at a high frequency for prolonged periods, resulting in their specialized histophysiological and biochemical organization. Of the two main types of fibres in these muscles<sup>1</sup>, the smaller red fibres are rich in myoglobin, mitochondrial substance, certain lipolytic and oxidative enzymes (lipoxidative), and function largely aerobically-metabolizing lipids as their chief energy fuel. The larger white fibres are poor in myoglobin, mitochondrial content, lipoxidative enzymes, rich in glycolytic enzymes, and function largely anaerobically-using glycogen as their major energy substrate. The red fibres perform slow and sustained contractions, while the white fibres are capable of relatively faster/short-lasting contractions. Certain birds and bats have been described as having only red fibres in their major flight muscle<sup>1</sup>. The metabolism of these red muscles has been closely identified with that of the usual red fibres of other muscles, as mentioned above. However, during our recent studies<sup>2</sup> on the exclusively red breast muscle of certain microchiropteran bats and weaver finches, we observed significant metabolic differences between the fibres of this muscle and the red fibres of the mixed muscles (having both red and white fibre types). Our observations are at variance with the usual metabolic speciation of the red fibres as predominantly fat-utilizing, aerobic components of muscle metabolism. We report results that suggest the distinct metabolic capacity of the pure red flight muscles to meet their energy requirements through both glycolytic and lipoxidative metabolic channels, quite unlike the fibres of other skeletal muscles. A possible correlation of such metabolic duality in these muscles with the specific flight physiology of the animals has been attempted.

### MATERIALS AND METHODS

The main flight muscle (m. pectoralis major) of certain microchiropteran bats (*Pipistrellus* sp.) and weaver finches (*Ploceus philippinus*) was used in the present study. Cryostat-cut 10  $\mu$  sections of

the fresh frozen muscle were processed for the histochemical demonstration of succinic dehydrogenase (SDH), lactic dehydrogenase (LDH),  $\alpha$ -glycerophosphate dehydrogenase ( $\alpha$ -GPDH), phosphorylase, lipids, glycogen<sup>3</sup>, and lipase<sup>4</sup>.

### OBSERVATIONS AND DISCUSSION

Cytologically, the fibres of the pectoralis muscle could readily be identified as the usual red ones<sup>2</sup> on the basis of their mitochondrial density—apparent in the preparation for SDH activity (Fig. 1 A)—and high myoglobin content, imparting an intense red colour to the muscle. Histochemical preparations revealed the presence of both glycolytic (Fig. 1 C, D) and lipoxidative (Fig. 1 A, B) metabolic components, and also that of lipids, glycogen and LDH activity<sup>2</sup>, uniformly in all the muscle fibres. Due to this histochemical uniformity it was not possible to differentiate the muscle fibres into specifically glycolytic and lipoxidative types, that are observed in mixed skeletal muscles.

Higher level of glycogen has been reported in the red than in white fibres of certain mammalian and avian skeletal muscles<sup>5-6</sup>. Hexokinase activity has also been reported<sup>7</sup> to be higher in red than in white muscle. Besides these, *in vitro* studies on the carbohydrate metabolism in predominantly red muscles have revealed their glycolytic capacity<sup>8-10</sup>. Yet, there seems to have been no attempt to investigate critically the glycolytic capacity of totally red skeletal muscles. In the house sparrow pectoralis, presence of glycogen and phosphorylase activity has been described in the fibres of the superficial region, while the fibres of the deeper region were found to be predominantly of oxidative type<sup>11</sup>. This, in a morphologically homogeneous red muscle both glycolytic and lipoxidative activities were demonstrated (though in different regions)—in direct relation to the specific mode of flight of the animal. Closely parallel to this are our observations. Though there is no distinction of fibres (and of their regional distribution) into glycolytic and lipoxidative populations, both types of metabolic components were present uniformly in all the fibres of bat (Fig. 1) and finch pectoralis. These fibres also showed uniform myosin-adenosine triphosphatase (m-ATPase) activity throughout the

\* Present address : Department of Zoology, Hans Raj College, University of Delhi.

muscle<sup>2</sup>, reflecting their identical pattern of contractility, since the m-ATPase activity of the muscle fibres is directly related to the speed of their contraction<sup>12</sup>. We have also observed that the intensity of the glycolytic activity in the fibres of the 'red' pectoralis of bats and finches is almost as high as in the white fibres of the typical skeletal muscle<sup>2</sup>.

FIG. 1. Histochemical demonstration of the enzymic components of glycolytic and lipoxidative metabolism in the major flight muscle (m. pectoralis major) of the microchiropteran bat. Both lipoxidative and glycolytic enzymes are shown to have uniform activity in all the fibres, which are all of one type. (A), succinate dehydrogenase activity; (B), (C), (D), activity of lipase, phosphorylase, and  $\alpha$ -glycerophosphate dehydrogenase respectively,  $\times 200$ .

Slow and fast contractions, in the pectoralis of most birds and bats, are the individual functions of red and white fibres—using mainly lipids and glycogen respectively. Thus, it seems only appropriate to elicit from our observations that the occurrence of both glycolytic and lipoxidative metabolic components uniformly in all the individual fibres of the 'red' pectoralis of the small microchiropteran bats and weaver finches (probably also in other birds having similar pectoralis) is an essential parallel of their capacity to perform both slow and fast contractions during flight. Physiological studies, using electromyographic recordings of the pectoralis muscle (composed exclusively of red fibres) of certain birds, have revealed the capacity of such 'red' fibres to perform both slow and fast contractions during flight<sup>13-15</sup>. We suggest that a physio-

logical shift from a fast to slow contraction (or vice versa) during flight is accompanied by a metabolic shift at cellular level—of which these 'red' fibres are quite capable since they possess both glycolytic and lipoxidative metabolic systems. Similar metabolic shift has been reported in dogs—where longer periods of muscular exercise showed gradual shift from carbohydrate to fat utilization<sup>16</sup>. It is likely that in the exclusively red pectoralis of bats and finches, energy derived from glycolysis is used during the short bursts of flight (requiring instant energy), while that from lipoxidative activity is utilized for relatively sustained flight. This interpretation however can be substantiated only by comparing the metabolic profile of the muscle at rest, as in the present study, with that of the muscle immediately after flight.

This, to our knowledge, is the first suggestion of the possible operation of both glycolytic and lipoxidative metabolic cycles within the same individual fibres of the exclusively red pectoralis of the active fliers. Evidently, a pure red muscle also possesses the metabolic equipment that is normally, and almost exclusively, characteristic of the white fibres of mixed skeletal muscles, suggesting thereby a local metabolic specialization of the muscle fibres in response to the specific flight physiology of the animals.

## LETTERS TO THE EDITOR

EFFECT OF MAGNETIC ACTIVITY ON NOON  
BITE-OUT AT KODAIKANAL—INFLUENCE  
OF SOLAR ACTIVITY

THE occurrence of a prominent trough accompanied by two maxima, one in the forenoon and the other in the afternoon in the diurnal variation of foF2 at equatorial latitudes referred to as noon 'bite-out', is a characteristic feature at stations that fall in the trough of the 'equatorial anomaly'. (Appleton, 1946; Bailey, 1948; Maeda, 1955; Rastogi, 1959). Sarma and Mitra (1956) studied the noon bite-out phenomenon by introducing two parameters:  $P_1 = (f_1 - f_2)/f_2$  and  $(f_3 - f_2)/f_2$ , where  $f_1$ ,  $f_2$  and  $f_3$  are the frequencies corresponding to the forenoon peak, midday trough and afternoon peak respectively in the diurnal variation of foF2. The ratio  $P_1/P_2$  is thus an index of the asymmetry in the noon bite-out effect. It was shown by Sarma and Mitra (1956) that the ratio  $P_1/P_2$  attains a value of unity at a particular sunspot number known as critical sunspot number which is found to increase with increase in magnetic dip. A later study by Raju and Rao (1959) for a number of equatorial stations indicated the critical sunspot number to increase with decrease in  $|L-I|$  where L and I are the geographic latitude and magnetic dip respectively. Bhargava and Subrahmanyam (1962) studied the influence of disturbed geomagnetic conditions on the noon-bite-out in foF2 at Kodaikanal for the period 1955–58 and reported the midday trough and the afternoon peak in foF2 to be reduced during disturbed conditions compared to quiet conditions, while the forenoon peak is more or less unaffected. This means the ratio  $P_1/P_2$  is high during disturbed conditions compared to quiet conditions.

In the present investigation, the effect of disturbed geomagnetic conditions on the asymmetry of the bite-out phenomenon at Kodaikanal (Geo. Mag, Lat.  $0.6^\circ$  N, Dip:  $3.5^\circ$  N) over the ascending phase of the solar cycle (1964–69) has been studied to infer the influence of solar activity. Published monthly ionospheric data of Kodaikanal for the period 1964–69 has been used for this purpose. For each month, the data have been divided into those of quiet conditions ( $\Sigma K_p \leq 10$ ) and disturbed conditions ( $\Sigma K_p \geq 25$ ) where  $K_p$  is the planetary K-index of geomagnetic activity. The median values of foF2 at half-an-hour intervals were calculated for both the periods separately from which the parameters  $P_1$ ,  $P_2$  and  $P_1/P_2$  have been evaluated. Median values of sunspot number corresponding to

the two periods have also been obtained for each month. Running averages were then calculated to smooth out short term and seasonal variations.

In Fig. 1 we show the variation of the ratio  $P_1/P_2$  with sunspot number for the quiet and disturbed periods separately. The following points may be

FIG. 1. Variation of  $P_1/P_2$  with sunspot number for quiet and disturbed conditions at Kodaikanal for the period 1964–69.

noticed. Although the ratio  $P_1/P_2$  shows a general tendency to increase with sunspot number, its behaviour during low and moderate solar activity periods is different in that it increases with sunspot number during low solar activity periods ( $R_s < 20$ ) and decreases during moderate solar activity periods ( $R_s > 100$ ). Further, the ratio  $P_1/P_2$  is high during magnetically disturbed conditions compared to quiet conditions during the periods of moderate solar activity ( $R_s > 100$ ), while the behaviour is exactly opposite during the periods of low solar activity ( $R_s < 20$ ) as can be clearly seen from Fig. 1. These observations are considered to be interesting in view of the following considerations.

The bite-out phenomenon is obviously the result of interaction and the relative role played by the production, loss and movements terms in the continuity equation of the electron density at the peak of the layer. The movements term includes the effects of vertical drift, horizontal diffusion of ionization along the field lines and neutral winds. Martyn (1955) and Rao (1967) showed that the forenoon peak in the diurnal variation of foF2 at equatorial latitudes is influenced by horizontal winds besides production and loss processes, while the afternoon peak is determined by vertical drifts and diffusion (Gliddon and Kendall, 1962). Since the

results of Bhargava and Subrahmanyam (1962) indicate that the forenoon peak is not much affected by magnetic activity, an attempt will now be made to account for the results of the present study, on a qualitative basis, in terms of vertical drifts, and horizontal diffusion besides production and loss processes. It is known that during disturbed conditions when the horizontal component of the magnetic field is subnormal, there will be a considerable lowering of the height of the layer due to vertical downward drift of plasma (effect of westward electric currents). As such, during periods of low solar activity when the vertical movements play a relatively important role, there should be considerable inhibition of loss of ionization due to lowering of the layer resulting in high values of  $P_1/P_2$  for disturbed conditions compared to quiet conditions, while there is not to be much of a difference between the values of  $P_1/P_2$  for disturbed and quiet conditions during relatively high solar activity periods. The observed result is exactly opposite to that expected on the conceived simplified picture of the origin of the noon bite-out phenomenon.

To sum up, the present investigation revealed a significant influence of solar activity on the relative trend in asymmetry in noon bite-out during quiet and disturbed conditions. This feature does not facilitate even a qualitative understanding in terms of vertical upward drift and subsequent horizontal diffusion of ionization along the field lines.

The authors are thankful to Dr. M. K. V. Bappu, for his interest in this work. The assistance of Mr. K. Sasidharan in the computations is thankfully acknowledged.

## LEVEL STRUCTURE OF $^{199}\text{Hg}$

DE-SHALIT<sup>1</sup> tested the applicability of the core-excitation model to  $^{199}\text{Hg}$  using the then available data and reported that the consistency of the model with regard to the magnetic moment and the transition rates are still to be tested. Hence in the present note the applicability of the core-excitation model to all the electromagnetic properties of first two excited levels is tested. In addition the properties are also compared with the estimations based on single particle as well as Kisslinger and Sorensen models<sup>2-4</sup>. Details of the calculations are given elsewhere<sup>5-7</sup>.

The core-excitation model in its simplest version envisages the levels in  $^{199}\text{Hg}$  as arising from the coupling of a  $p_{3/2}$  neutron to the first  $2^+$  state of the  $^{198}\text{Hg}$  core. In these calculations recent experimental data are taken<sup>8-10</sup>. The following parameters gave the best fit :

$$g_p = 0.75 \text{ [Schmidt value, } \mu/\sqrt{I(I+1)}]$$

$$A^2 = 0.988$$

$$g_c = 0.4 \text{ (= } Z/A \text{) and}$$

$\langle O(T_c^2) \rangle = 0.179$  (average value of  $^{198}\text{Hg}$  and  $^{200}\text{Hg}$ ). The value of  $A^2$  is very close to 1 in conformity with the requirement of the core-excitation model. The results are tabulated in Table I.

As can be seen from Table I, an excellent agreement is obtained between the predictions of core-excitation model and the corresponding experimental

### A STUDY OF MOLECULAR FORCE FIELD ELLIPSES FOR $\text{SnCl}_2$ WITH LONE-PAIR

The stannous dichloride is a typical example of  $\text{XY}_2$  type of molecules and is of particular importance in the studies of lone-pair Chemistry. Considerable information on the vibrational frequency data of  $\text{SnCl}_2$  is available in the literature<sup>1,2</sup>. The object of the present note is to report the investigations made by us on the molecular vibrations of  $\text{SnCl}_2$  based on Green's function and Partitioning (GFP) techniques<sup>3</sup>.

The method used, which is reported earlier<sup>4-6</sup>, involves the following product and sum rules of frequencies for the isotopic substitution  $\text{XY}_2\text{L} \rightarrow \text{XY}_2^*\text{L}$  for  $\text{SnCl}_2$ , with lone-pair electron contributions:

$$\omega_1^{*2} \omega_2^{*2} = \left( \frac{\sigma}{\alpha^2 \epsilon - \sigma} \right) \left( \frac{m_y}{m_y^*} \right)^2 \omega_1^2 \omega_2^2 \quad (1)$$

$$\omega_1^{*2} + \omega_2^{*2} = \left[ \frac{\sigma C^2 + \alpha^2 \epsilon}{C^2 (\alpha^2 \epsilon - \sigma)} \right] \left( \frac{m_y}{m_y^*} \right) \omega_1^2 + \left[ 1 - \frac{\alpha^2 \epsilon}{C^2 (\alpha^2 \epsilon - \sigma)} \right] \left( \frac{m_y}{m_y^*} \right) \omega_2^2 \quad (2)$$

$$\epsilon = \frac{m_y - m_y^*}{m_y^*}, \quad \sigma = \frac{m_y^* m_x \epsilon}{m_y d_1^2} + 1,$$

$$\alpha = \frac{\sqrt{2 m_y m_y^{*3/2}}}{[m_y^* m_x - m_e m_y] d_s}$$

$$C^2 = 1 - c^2, \quad d_1^2 = \frac{1}{m_y} [m_x m_y^4 - 2 m_y m_y^* + m_x m_e]$$

$$d_s = \left[ \frac{m_y^* m_x}{m_x m_y^* - m_y m_e} \right]^{1/2} d_1$$

The experimental frequency assignment for  $\text{SnCl}_2$  is ambiguous in fixing the valence angle and deciding whether  $\omega_1 > \omega_2$  or *vice versa*. Our study on  $\text{SnCl}_2$  reveals that the mixing parameter becomes imaginary for the case  $\omega_1 < \omega_2$ , unless  $\omega_1^*$  has a frequency assignment in the range  $325 \text{ cm}^{-1}$  to  $329 \text{ cm}^{-1}$ , but then this value of  $\omega_1^*$  is not correct as per the IR spectra reported by Andrews *et al.*<sup>7</sup>. Hence we conclude  $\omega_1 > \omega_2$ , which is in agreement with the conclusion drawn from the electronic spectrum of  $\text{SnCl}_2$  by Naegeli *et al.*<sup>11</sup>.

The molecular force field ellipses for  $\text{SnCl}_2$  have been obtained for valence angles  $90^\circ$ ,  $95^\circ$ ,  $100^\circ$  and  $120^\circ$  for (1)  $\omega_1 = 354.8 \text{ cm}^{-1}$ ,  $\omega_2 = 120 \text{ cm}^{-1}$ ,  $\omega_3 = 334.6 \text{ cm}^{-1}$ , (2)  $\omega_1 = 334.6 \text{ cm}^{-1}$ ,  $\omega_2 = 120 \text{ cm}^{-1}$ ,  $\omega_3 = 354.8 \text{ cm}^{-1}$  and a few are given in Figs. 1 and 2. From the study of the ellipses, it is observed that for a given valence angle the lone-pair electron contribution causes the eccentricity to increase; while the angle of inclination of the ellipse with the  $F_{11}$  axis decreases considerably. This is an interesting feature which implies that the inclusion of lone-pair is as if there is an increase in the mass of the central atom and which follows from the analysis of molecular force field ellipses by Torkington<sup>10</sup>.

Note : a, b, c and d refer to bond angles 90°, 95°, 100° and 120° respectively.

FIGURE 2

$\omega_1 < \omega_3$

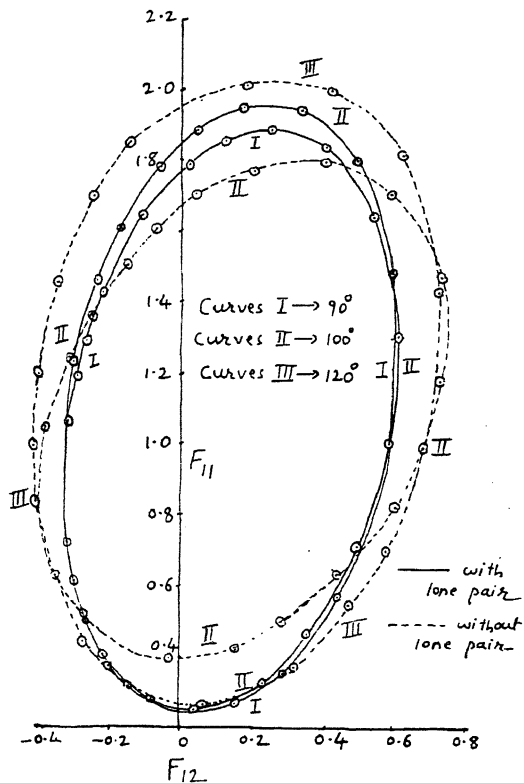

Fig. 2.  $F_{11}$  as a function of  $F_{12}$  for  $\omega_1 < \omega_3$ .

In the case  $\omega_1 > \omega_3$ , using equations (1) and (2) together with  $\omega_1^4 = 352.3 \text{ cm}^{-1}$  (reported value<sup>1</sup>), the mixing parameter comes out to be imaginary. Therefore by selecting  $\omega_1^4 = 346.5 \text{ cm}^{-1}$  (from the IR spectra<sup>1</sup>) and by varying the mixing parameter we arrive at a consistent set of molecular constants given in Table I.

# VARIATION OF INTERNAL PRESSURE WITH TEMPERATURE IN LIQUID OXYGEN, ARGON, NITROGEN AND METHANE

RECENTLY, Suryanarayana<sup>1</sup> brought out the thermodynamic significance of internal pressure and in a private communication stated that the internal pressure should fall exponentially with increase in temperature. This aspect is verified in the present investigation by examining the data of internal pressure of oxygen, argon, nitrogen and methane in their liquid state. The method of calculation of internal pressure is based on the method given by Suryanarayana (*loc. cit.*). The equation used is

$$\pi = \frac{T\alpha}{\beta_T}$$

where  $\alpha$  is the thermal coefficient of expansion,  $\beta_T$  is isothermal compressibility and  $T$  is the absolute temperature. The data for all these liquids have been obtained from Rowlinson<sup>2</sup>. The plots of  $\ln \pi$  versus the absolute temperature are presented in the graph. As predicted by Suryanarayana (*loc. cit.*) all plots are clearly linear and  $\ln \pi$  decreases with increase of temperature.

In the case of oxygen the plot is made up of two straight lines. A very interesting observation in the case of oxygen is that in the region of 60° to 75° K, the internal pressure varies very little with temperature. Several other data of oxygen presented by Russell B. Scott<sup>3</sup> in the same range of temperatures do not give a clue to this behaviour of oxygen between 60° to 75° K. The experimental results of Kandra, Haseda and Otsubo<sup>4</sup> on the paramagnetic susceptibility of solid and liquid oxygen show no abnormality in this region.

A plot of  $\ln P_{exp}$  versus internal pressure also exhibits an abnormal trend in this range of temperature. The data of the variation of viscosity with temperature postulated by Rudenko and Shubnikov<sup>5</sup> give a similar abnormal variation of viscosity with temperature in the same range. The data on the variation of dielectric constant with temperature of Warlaw Warner and Keesom<sup>6</sup> show a similar abnormality in the same range of temperature.

The only plausible explanation seems to be that in this condensed region there seems to be some weak transient association of oxygen molecules forming the polymer  $O_4$ , which is said to be responsible for the blue colour of liquid and solid oxygen. Oxygen has the outstanding difference from most other fluids in its being strongly paramagnetic. Thus  $O_2$ ,  $O_4$  mixtures and equilibria due to different proportions of these constituents could perhaps explain an overall cancellation effect by which the internal pressure remains almost constant.

The authors thank Dr. C. V. Suryanarayana and Mr. J. Kappusami, CECRI, Karaikudi, for useful discussions. They also thank Dr. V. C. Kulandaiswamy, Director of Technical Education, Government of Tamil Nadu and Professor S. Srinivasan, Principal, ACCET, for their encouragement.

## CONDUCTOMETRIC STUDY OF $CdI_2$ -KI SYSTEM

CONDUCTIVITY measurements by Van Rysselberghe and Nutting Lee<sup>1</sup> of mixtures containing  $CdI_2$  and KI showed large deviations from the mixture rule, suggesting ion-pair formation. Satyavati *et al.*<sup>2</sup> studied the ultrasonic velocity and adiabatic compressibility of  $CdI_2$ -KI mixtures in aqueous medium and concluded from the results that the formation of the complex ion  $CdI_4^{--}$  is most likely. Raman spectra of cadmium halides in aqueous solutions of alkali halides examined by Woodward and co-workers<sup>3</sup> have also indicated the presence of an ion-pair of the type  $CdX_4^{--}$ .

This paper describes the conductivity measurements of solutions of  $CdI_2$  and KI individually and together in aquo-organic solvents, measured under varying conditions to establish the structure of the ion-pair formed in such solutions, and the stability constant from the data thus obtained.

**Results and Discussion.**—Cadmium iodide and potassium iodide used in the experiments were of Analar grade and the solutions of electrolytes of required concentration were prepared either in conductivity water or 75% (V/V) methanol in conductivity water. The methanol (Extrapure, Merck) was distilled twice before use. Conductometric measurements were made using Toshniwal Conductivity Bridge (Model: CL 01/01) and a dip type conductivity cell. The accuracy of the instrument is  $\pm 2\%$ . All measurements were made at 30° C.

The conductivity of the mixture of  $\text{CdI}_2$  and KI was always less than the sum of the conductivities of  $\text{CdI}_2$  and KI taken separately at constant volume indicating ion-pair formation. The molar composition of the ion-pair was determined by Job's method of continuous variation<sup>4</sup>, for equimolar solutions in the concentration range 0.03 M to 0.07 M. The deviation of conductivity,  $\Delta\lambda = \lambda_1 + \lambda_2 - \lambda_3$ , (where  $\lambda_1$  is the conductivity of a series of  $\text{CdI}_2$  solutions and  $\lambda_2$  that of KI solutions,  $\lambda_3$  that of the mixture of  $\text{CdI}_2$  and KI), was plotted against the ratio  $[\text{CdI}_2]/\{[\text{CdI}_2] + [\text{KI}]\}$ . The plots obtained (Fig. 1) clearly show that the ion-pair contains one molecule of  $\text{CdI}_2$  and two molecules of KI. These are in agreement with the results of the earlier workers<sup>2,3</sup>.

FIG. 1. Job's plot for  $\text{CdI}_2$ -KI system in aqueous medium at 30°C. Concentration of the mixture A—0.03 M; B—0.05 M; C—0.07 M.

FIG. 2. Job's plot for  $\text{CdI}_2$ -KI system in 75% (v/v) methanol at 30°C. Concentration of the mixture A—0.01 M; B—0.03 M; C—0.05 M.

The above procedure was repeated in 75% (V/V) methanol solutions in water with electrolyte concentration ranging from 0.01 to 0.05 M. The data so obtained are given in Fig. 2. These curves indicate that the ion-pair contains  $\text{CdI}_2$  and KI in the ratio of 1:1. Hence, we propose that the

ion-pair formed is of the type  $\text{CdI}_3^-$ . The equilibrium may be represented as:

The stability constant of the above has been calculated by the method of Hegenmuller<sup>5</sup>. For two mixtures of molarity  $M_1$  and  $M_2$ , where the concentrations are not very different, the corresponding instability constant ( $k$ ) is given by

$$k = \frac{(M_1/2 - Z_1)^2}{Z_1} = \frac{(M_2/2 - Z_2)^2}{Z_2} \quad (1)$$

where  $Z_1$  and  $Z_2$  are the concentrations of the complexes at the maxima of the continuous variation curves in the two systems. From Equation (1) we get

$$Z_2 = \frac{M_1 - M_2}{2(a-1)} \pm \frac{aM_2 - M_1}{2(a-1)\sqrt{a}} \quad (2)$$

where  $a = Z_1/Z_2$ . Minus sign was used for  $M_2/2 > Z_2 > 0$  and  $M_1/2 > Z_1 > 0$ . Since the heights of the maxima ( $Z_1$  and  $Z_2$ ) of the continuous variation curves could be found for the two mixtures, it is possible to calculate  $a$  and hence  $Z_1$  and  $k$ . The stability constant  $K$  is therefore given by

$$K = 1/k = 1.6 \pm 0.2 \times 10^3 \text{ and } pK = -3.20 \pm 0.06.$$

From the relationship  $-\Delta G^\circ = RT \ln K$ , the free energy of formation was found to be  $-4.44 \pm 0.09 \text{ kcal.mole}^{-1}$  at 30°C.

The stability constant was also determined by extrapolation of Job's curves as suggested by Raghavarao and coworkers<sup>6</sup> using the expression,

$$K = \frac{1-a}{a^2 \cdot C}$$

where  $a$  is the degree of dissociation and 'C' is concentration. The values thus found are as follows:

$K = 2.0 \pm 0.3 \times 10^3$  and  $pK = -3.30 \pm 0.06$ . These values are in close agreement with those obtained by using Hagenmuller's method<sup>5</sup>.

The authors wish to thank Prof. N. V. Subba Rao, for his keen interest and encouragement.

# SPECTROPHOTOMETRIC DETERMINATION OF COPPER (II) USING 1-(2-PYRIDYL-AZO)-2-PHENANTHROL (PAP) AS A CHROMOGENIC REAGENT

ANALYTICAL applications of a large number of heterocyclic azo dyes have been reviewed<sup>1,2</sup>. 1-(2-Pyridylazo)-2-phenanthrol (PAP), a chelating agent<sup>3,4</sup> forms pinkish-red coloured complex immediately on mixing with copper(II). A stock solution of PAP (0.001 M) was prepared by dissolving it in methanol. Cu(II) stock solution was prepared by dissolving  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  (AnalaR, B.D.H.) in doubly distilled water and it was standardised gravimetrically. All other chemicals used were of reagent grade. 1,4-Dioxan was refluxed for about 5 hours over sodium metal and then distilled fresh before use.

A Unicam, SP-600, spectrophotometer was used for absorbance measurements and a Metrohm pH meter, E-350, for measuring pH's.

The pinkish-red, water-insoluble complex is extractable in various organic solvents, such as chloroform, carbon tetrachloride and benzene. The complex is soluble in 70% (v/v) methanol but the precipitate appears after a few minutes. To keep the complex and reagent in solution water: methanol: dioxan (35:50:15) medium was used. It was found that dioxan does not affect the absorbance of the complex even if present in larger quantities (up to 30%). The complex was found to be stable for 72 hours, after which measurements were discontinued.

The absorbance of the complex, which shows maximum at 560 nm, remains constant in the pH range 2.2–8.0 and above pH 8.0 and below pH 2.2, absorbance falls. A mole ratio study revealed that for full colour development twice the calculated amount of the reagent, PAP, is required. In subsequent work, five times molar excess of the reagent was maintained. The system obeys Beer's law up to 3.2 ppm of copper. Optimum concentration range for the determination of copper, evaluated by Ringbom's plot has been found to be 0.54 to 2.39 ppm. The sensitivity of the colour reaction (in terms of Sandell's definition) is  $0.0020 \mu\text{g Cu/cm}^2$  at 560 nm. The molar absorptivity is  $3.0 \times 10^4 \text{ mol}^{-1} \text{ cm}^{-1}$ . The apparent instability constant, calculated from mole ratio plot, was found to be  $8.3 \times 10^{-6}$  at room temperature. The mole ratio method, slope ratio method and Job's method of continuous variations suggest that 1:1 [Cu(II):PAP] complex is formed in the system.

Synthetic solutions containing known amounts of copper (1.08 ppm) and varying amounts of diverse

ions were prepared and copper was determined in their presence at pH 3.0. The amounts of ions and anions, given in parentheses in ppm, did not cause deviation of more than 3% in absorbance:  $\text{PO}_4^{3-}$  (160),  $\text{Cl}^-$  (1000),  $\text{Br}^-$  (800),  $\text{I}^-$  (664),  $\text{NO}_3^-$  (620),  $\text{SO}_4^{2-}$  (200), oxalate (10), tartrate (640), citrate (380), thiourea (100),  $\text{CNS}^-$  (100),  $\text{Cr}(\text{III})$  (400),  $\text{Sr}^{2+}$  (200),  $\text{Ca}^{2+}$  (200),  $\text{Ba}^{2+}$  (200),  $\text{Mn}^{2+}$  (100),  $\text{La}^{3+}$  (14),  $\text{Th}(\text{IV})$  (15),  $\text{P}(\text{IV})$  (39),  $\text{Ru}(\text{III})$  (10),  $\text{Os}(\text{VIII})$  (5). However, EDTA inhibits colour formation while  $\text{S}_2\text{O}_3^{2-}$ ,  $\text{F}^-$ , Fe(II and III), Hg(II),  $\text{Ni}^{2+}$ ,  $\text{Co}^{2+}$ , V(V), U(VI),  $\text{Cd}^{2+}$ ,  $\text{Zn}^{2+}$ , Rh(III) and Pd(II) interfere seriously. Interference due to 5 ppm each of  $\text{Cd}^{2+}$ , V(V), U(VI), Pd(II) and Rh(III) was removed by adding 50 ppm of the citrate. Mercury (10 ppm) was masked with iodide, while Fe(II and III) (5 ppm) with tartrate (50 ppm). Attempts to mask  $\text{Ni}^{2+}$ ,  $\text{Co}^{2+}$  and  $\text{Zn}^{2+}$  were unsuccessful.

**Recommended Procedure.**—To a suitable aliquot of solution containing between 5.4–23.9  $\mu\text{g}$  of copper, is added five times molar excess of reagent (PAP) in methanol. The pH of the solution is adjusted between 2.2–8.0 using sodium acetate-acetic acid buffer and the total volume is made to 10 ml with doubly distilled water, maintaining 50% methanol and 15% dioxan medium (to keep the complex and the reagent in solution). The absorbance is measured at 560 nm against the corresponding reagent blank and the amount of copper is deduced from the calibration curve.

The authors are thankful to the Council of Scientific and Industrial Research, India, for the award of a Research Fellowship to one of them (A. K. R.).

ON THE OCCURRENCE OF SOME JURASSIC  
NODOSARIOID FORAMINIFERA FROM THE  
MANFARA DOME SECTION OF THE WAGAD  
HILL BLOCKS, EASTERN KUTCH

ALTHOUGH exposures of the Mesozoic rocks have long been known from the Wagad hills of the eastern Kutch, very little has been published on its microfaunal contents. The more recent work on the Wagad rocks is that of Biswas (1971) and Deshpande (1972). Based on the stratigraphical and structural studies of this region, Deshpande (*op. cit.*) has proposed a detailed and revised stratigraphical classification. The present authors who have taken up the study of Wagad rocks with a view to investigate its microfaunal contents have followed Deshpande's classification.

The Adhoi Member of the Kanthkot Formation is exposed in the Manfara Dome section (23° 30', 70° 24') in the westernmost part of the Wagad hills. In this section, the Adhoi Member is represented by 20 meters of grey to khakhi coloured siltstones and shales. The base of this member is not exposed here, while it is overlain disconformably by a conspicuous hard calcareous sandstone band studded with megafossils of *Astrate*, *Trigonia*, *Pleuromya*, *Pholadomya*, *Pinna*, etc.

The shales and silts of Adhoi Member were processed in the laboratory and a study of its microfaunal assemblage has revealed twelve genera and nineteen species of *Nodosarioid* foraminifera.

This foraminiferal assemblage is being reported by the authors for the first time. The fossils recognised and identified are as under:

*Robulus* sp.; *R. Carinocordatus* (Subottina and Srivastava); *R. stephensoni* (Cushman); *Lenticulina dilectaformis* (Subottina and Srivastava); *L. navicula* (d' Orbigny); *Palmula* sp.; *Astacolus calliopsis* (Reuss); *A. renominata* (Schwager); *A. centrogyrata* (Terquem); *Saracenaria* sp.; *Marginulina* sp.; *Vaginulinopsis hybrida* (Terquem); *Dentalina gracilis* (d' Orbigny); *Nodosaria* sp.; *Nodosaria affinis* (Reuss); *Rectoglandulina oviformis* (Terquem); *Pseudoglandulina* sp.; *Lagena* sp.; *Lagena hispida* (Reuss).

In the above assemblage, various species of *Robulus* constitute 36%, *Astacolus* 13%, *Rectoglandulina* 11% and *Lagena* 10%; while the rest is made up of the remaining *Nodosarioid* species. In addition to these forms, a few species of Ostracodes and some doubtful Bryozoans have also been noted. On the whole, ostracodes present less varieties of species than the *Nodosarioid* foraminifera.

The most striking features of Manfara dome microfauna are: (i) the occurrence of several species of a single family of *Nodosariidae*, (ii) forms with radiate, glassy, calcareous indistinctly trans-

parent shell material often resembling milk glass—characteristic of the Triassic and Jurassic *Nodosarioid* foraminifera which Brotzen (1963) prefers to call the "mesonodosarioid" stage in the *Nodosarioid* evolution, and (iii) a general absence of other foraminiferal families.

Some of these species and genera along with many other foraminiferal families have been reported from the other localities of Kutch Mesozoic (Agrawal and Singh, 1961) from the exposures of Habo series at Walkhawas Tank and Fakirwari village and by Subottina *et al.* (1960) from the Lodia village and Khawada.

Based on their studies of these fossils, the authors have proposed an Upper Callovian-Oxfordian age to the siltstone-shaly facies of the Adhoi Member of the Manfara Dome section.

Paleoecology of these fossils is rather difficult to interpret as very little is known about the ecology, living habits and the physiology of their living representatives.

General absence or the lack of development of other foraminiferal families in this area needs further investigation. A detailed study of this area is under progress and more exhaustive description of these forms along with biostratigraphical and paleoecological interpretations will be published in due course.

The authors are thankful to Professor S. S. Merh for many useful discussions and a critical scrutiny of the text of this paper. They also gratefully acknowledge the help rendered by Dr. S. V. Deshpande of O.N.G.C.

CHONDRITES, STERNBERG, A TRACE FOSSIL  
FROM THE DALMIAPURAM FORMATION,  
TRICHINOPOLY DISTRICT, S. INDIA

PRESENT note records the first ever find of *Chondrites* Sternberg in India. It is collected from the Grey Shale horizon in the Dalmiapuram Formation<sup>1-3-9</sup> near Kallakudi.

Genus *Chondrites* Sternberg, 1833 (non McCoy  
1848)  
*Chondrites* sp.

FIG. 1. *Chondrites* sp.,  $\times 1$ .

**Material :** 3 slabs ; figured specimen No. K1 8/72.  
**Dimensions :** Diameter of tunnel 2 mm.

**Description :** These are feeding burrows with plant-like branching tunnels of constant diameter (2 mm) and a circular cross section. Tunnels are filled partly with loose grey sand particles, which but for a darker shade, are like the surrounding matrix, and partly with pellet-like grains more or less transverse to the tunnel length and may be the faecal pellets as mentioned by Häntzschel<sup>5</sup>.

**Remarks :** Much smaller diameter distinguishes this species from *Chondrites* sp. from the Upper Cretaceous of Austria as figured by Häntzschel<sup>5</sup> ; while *C. bellensis* Zieten from the Lower Jurassic of Rolzmaden, Germany<sup>6</sup>, has besides a larger diameter a much more crowded system of tunnels.

The genus *Chondrites* ranging from Cambrian to Tertiary does not shed much light on the age of the Grey Shale horizon. But as a *Fodichnia* of Seilacher's *ethological* group of Trace Fossils and falling in his *Nereites facies* indicates, littoral to very shallow water deposition of the grey shales, presence of minute grains of pyrites and marcasite pointing to somewhat oxygen poor surroundings.

**Age :** The more probable age for this horizon appears to be Upper Aptian to Lower Albian<sup>1-3</sup> as indicated by ostracods and foraminifers rather than Hauterivian to Barremian<sup>4</sup>.

**Occurrence :** Grey Shale horizon at Kalkkudi.

**Repository :** The material is deposited in the Department of Geology and Palaeontology of the Maharashtra Association for the Cultivation of Science, Poona-4.

#### NOTE ON THE AQUITANIAN SEDIMENTS OF VINJHAN-MIANI AREA, SOUTHWESTERN KUTCH, GUJARAT

IN Vinjhan-Miani, the fossiliferous limestones and marls belonging to the Lutetian age (Kirthar) are found grading upwards into hard, dark brown coloured marls, which, though lithologically very similar to the underlying Lutetian marls, are easily distinguished from the latter by their different fossil content. The above sequence of beds is exposed about 1 km ENE of Khirasara village.

The overlying marls contain a peculiar type of lamellibranch shells which express affinity with the genus *Pecten*. The characteristic larger foraminifera (*Nummulites*, *Discocyclina*, *Fasciulites*, etc.) as well as its distinctive planktonic foraminifera of the underlying Lutetian do not extend into this horizon.

Thin section studies of the samples of this marl bed have further revealed the presence of *Spiroclypeus ranjanae* Tewari in abundance (Figs. 1, 3) along with rare *Lepidocyclina* (*Lepidocyclina*) sp. (Fig. 2). Typical Oligocene forms like *Nummulites fichteli*, *N. intermedius*, *N. clipeus*, *Lepidocyclina* (*Eulepidocyclina*) sp. and *Miogyopsinoides complanata* (Raju et al., 1970, p. 162) are absent in it. Since the occurrence of *Spiroclypeus ranjanae* has been noted in the Aquitanian beds of Waior in association with *Miogyopsina* S.L., *Miogyopsina* (*Miogyopsinoides*) *dehaarti*, *Lepidocyclina* (*Nephrolepidina*) *sumatrensis*, L. (*Nephrolepidina*) *borneensis*, *Miogyopsina* (*Miogyopsina*) *irregularis*, *Austrotrillina howchini*, etc. (Tewari, 1959), the Aquitanian age for *Spiroclypeus ranjanae* seems favourable. The work of Eames, Banner, Blow and Clarke (1962), who reported this form and *Miogyopsina* together from the Asmari Limestone (Aquitanian), lends support to the Aquitanian age of *Spiroclypeus ranjanae*. In the absence of definite

Oligocene foraminifera, *Spiroclypeus ranjanae* is suggested to be of Aquitanian age; and, as a consequence, the overlying marl horizon with *Spiroclypeus ranjanae* and the lamellibranch shells having affinity with *Pecten* may be dated as Aquitanian.

Figs. 1-3. Figs. 1, 3. *Spiroclypeus ranjanae*, Fig. 1, axial Section; Fig. 3, equatorial section,  $\times 35$ . Fig. 2. *Lepidocyclina* (*Lepidocyclina*) sp., equatorial Section,  $\times 35$ .

The contact between the underlying Lutetians and the overlying Aquitanians is disconformable (see Table I).

TABLE I

|                    |  |
|--------------------|--|
| Aquitanian         | Dark brown, hard, fossiliferous marl bed studded with lamellibranch shell showing affinity with <i>Pecten</i>  |
|                    | ----- Disconformity -----  |
| Lutetian (Kirthar) | Fossiliferous light yellow marl and limestone with <i>Nummulites Fasciolicus</i> , <i>Discocyclina</i> , etc. and Lutetian planktonic foraminifera; unfossiliferous khaki shales and bauxite and conglomerates |

In the light of the aforesaid facts, it can be remarked that:

(a) in Vinjhan-Miani, the Lutetian rocks are directly overlain by the sediments referable to the Aquitanian age;

(b) the presence of Aquitanian directly over the Lutetian suggests that the Oligocene (Nari) is absent in the area under study;

(c) the aforesaid faunal differences observed in the overlying horizon, namely, the presence of lamellibranch shells of *Pecten* affinity, the presence of *Spiroclypeus ranjanae*, and the absence of larger and smaller (planktonic) Lutetian foraminifera, clearly establish this horizon as a separate ecological as well as time rock unit. The fauna in this bed indicates deposition in a very shallow neritic environment, i.e., from the low tide mark down to a depth of 20 metres, where the bivalves are able to survive very suitably. This environment of deposition also makes this horizon distinct from the underlying Lutetians in which the deposition appears to be controlled by the central shelf conditions (40 to 80 m).

The writer expresses his indebtedness to Prof. R. C. Misra. Dr. S. N. Singh, and Dr. K. P. Vimal for their able suggestions and encouragement. He is also indebted to his mentor, Dr. Pratap Singh, for the help in the preparation of this note. This study is being supported by the State Council of Scientific and Industrial Research grant SCSIR/1883/LKO(45)/72.

#### LOWER AND MIDDLE STONE AGE TOOLS FROM PALGHAT DISTRICT (KERALA)

Two Palaeolithic sites have been discovered in Palghat District on the upper region of Kanhirapuzha and Malampuzha rivers.

Collection from Kanhirapuzha river bed comes from the pebble deposit. In this, there are two Hand-axes of the Lower Palaeolithic culture (Figs. 1 and 2) made on gneiss rock. The tools are made on pebbles. Such tools have been reported from Karnataka<sup>1</sup> and they are compared with 'Larsen Type'<sup>2</sup> of South Africa.

Middle Palaeolithic tools (Fig. 3) were obtained from Malampuzha region, which include borers, flakes and fluted cores of quartz. Borers show the character of 'Teri Type' and one among

them is a scraper-cum-borer type. Retouches are seen on the sides and at the end of the borers. On the flake the positive bulb-of-percussion is very prominent.

Figs. 1-2

FIG. 3

This is perhaps for the first time that the Stone Age Sites have been discovered in Kerala.

#### VARIATIONS IN CHEMICAL CONSTITUENTS OF BLOOD PLASMA OF *CLARIAS BATRACHUS* (L.) DURING STARVATION

BILINSKI AND GARDNER<sup>1</sup> showed a more significant increase in the concentration of free fatty acids in blood plasma of rainbow trout in the first two weeks of fasting. In the present study changes in total protein, albumin, globulin, fibrinogen, non-protein nitrogen, iron, calcium, cholesterol, total phosphorus in plasma and glucose in whole blood are recorded at different intervals of starvation.

Fifty fishes of size 20-25 cm were put in a large glass aquarium (90 × 45 × 40) containing tap

water. They were fed four days before starting the experiment. Sampling was done after 1, 2, 5, 10, 15, 30, 45, 60, 75 and 110 days of fasting. On each sampling day five fishes were sacrificed. Throughout the period of experiment, temperature of the aquarium water ranged from 20° C to 35° C. Water of the aquarium was changed every day. There was no mortality of fishes during the period of experiment. Blood was collected after severing the caudal peduncle of the fish. For checking coagulation double oxalate anti-coagulant at the concentration of 4 mg/2 ml of the blood was used. After taking the required amount of the whole blood for the analysis of glucose, it was quickly centrifuged at 3,500 rpm for 15 minutes.

The techniques described by Oser<sup>2</sup> were adopted for the estimation of various chemical constituents.

Total protein, albumin, globulin, fibrinogen, total phosphorus, glucose, iron and calcium showed similar pattern of changes during starvation (Fig. 1).

FIG. 1. Variations in chemical constituents in the blood plasma of *C. batrachus* during starvation.

The maximum values were recorded on the second day of starvation, thereafter values decreased gradually. In non-protein nitrogen a gradual fall

was noted. A large increase in the concentration of cholesterol was noted upto 15th day, thereafter the values decreased gradually.

Variations in chemical constituents were due to haemoconcentration and haemodilution. During early days of fasting, the body tissues became more acidic and absorbed water from the blood, and increased the concentration of chemical constituents in the blood<sup>2</sup>. But during later days the mechanism was reversed, where, the release of water from the tissues to the blood resulted in the haemodilution. During starvation stored materials are utilized for basal metabolism and consequently, the concentration of different chemical constituents is diminished.

It can be concluded that during prolonged period of starvation fish acclimatizes itself and its resting metabolism decreases markedly. Initially there is a rapid fall in the concentration of various constituents of the plasma, and as soon as the fish adjusts itself, the decrease becomes gradual and in this way fish endures a prolonged period of starvation.

Grateful acknowledgement is made to Dr. A. Q. Siddiqui for valuable help and advice.

#### TISSUE SPECIFICITY OF GLYCOGEN SYNTHESIS IN SCORPION *HETEROMETRUS FULVIPES*

STUDIES on the physiology and biochemistry of arachnids have received cursory attention, and there are very few reports on glycogen synthesis in the scorpion<sup>1</sup>. The distribution of biochemical constituents and incorporation of labelled glucose into glycogen in tissues of the South Indian field scorpion, *Heterometrus fulvipes* (Koch), showed tissue specific glycogen metabolic potential in this animal<sup>1,2</sup>. It seems necessary to obtain information about the tissue specificity of glycogen synthesis.

The collection of the scorpions, their maintenance and isotope uptake have already been described<sup>1,2</sup>.

$$\text{Tissue somatic index} = \frac{\text{Tissue wet weight (g)} \times 100}{\text{Total animal wet weight (g)}}$$

Tissue somatic indices of scorpion show variations. They are in the order, Hepatopancreas < Muscle < Ovary (Table I). It is evident that hepato-

pancreas constitutes more than a quarter of the whole body wet weight. This is appreciable since the hepatopancreas, which parallels insect fat body and vertebrate liver, is found to be the important site for biochemical reactions<sup>3</sup>.

In striking contrast to vertebrates, where muscle constitutes about 45% of total body wet weight<sup>4</sup>, the somatic index of muscle of scorpion is only 10.6. From its synthetic ability and carbohydrate content, it has been suggested<sup>1</sup>, that muscle in scorpion does not contribute to the general metabolic pool of the animal. The ovarian somatic index is only 3.7, but the period in which the experiments were performed (February-early March) is the breeding period for *H. fulvipes* which is reflected by its high glycogen content<sup>1,2</sup> and active glycogen synthesis (Table I). However the tissue somatic index has been shown to vary with the season as well as with the physiological state of the animal<sup>5,6</sup>.

TABLE I  
Tissue somatic index, unit activity (counts/min/  
glycogen in gram fresh tissue) and tissue activity  
(counts/min/total glycogen present in whole  
tissue) in various tissues of scorpion

| Tissue         | Number of<br>observations<br>made | Tissue somatic<br>index | Unit activity | Tissue activity |
|----------------|-----------------------------------|-------------------------|---------------|-----------------|
| Hepatopancreas | 7                                 | 27.90                   | 2000          | 2740            |
| Muscle         | 6                                 | 10.61                   | 625           | 326             |
| Ovary          | 6                                 | 3.72                    | 748           | 136             |

Glycogen synthesis in various tissues was also found to vary (Table I). Activity was recorded at 18 hours after the administration of U-C<sup>14</sup> glucose, and this period was found to be optimum for incorporation<sup>1</sup>. When activity was considered for total glycogen present in gram fresh tissue, hepatopancreas is shown to have the highest synthetic ability followed by ovary and muscle. Even when specific activity was considered, the same trend was observed<sup>1</sup>. However, in order to get a true picture of the glycogen synthetic potential of various tissues, the activities have been expressed for total glycogen present in the whole tissue. This expression is known to give a clear picture of the contribution of a tissue to the whole animal metabolism<sup>4</sup>. Data presented indicate that the activity is in the order, Hepatopancreas < Muscle < Ovary. This is interesting since the activity considered for glycogen present in gram fresh tissue showed that the activity of ovary exceeds the activity of muscle. It appears that though the animal is in vitello-

genesis, it does not seem to have a high glycogen synthetic potential as has been observed in insects, which accumulate large amounts of glycogen during vitellogenesis<sup>7</sup>. This high level of carbohydrate content has been shown to facilitate the utilization of dietary proteins in the blow-worm, *Phormia*<sup>8</sup>. The lower synthesis of glycogen in ovary and high synthesis in hepatopancreas indicate a possible mobilization of sugars from hepatopancreas to ovary, since such preferential channeling of energy from visceral tissue to gonadal tissues during reproductive phase is not rare in arthropods<sup>9</sup> and vertebrates<sup>10</sup>.

three developmental stages: tadpoles without legs, with fore limbs, and with both fore and hind limbs. Adult frogs were also collected from the same area. Liver, muscle, kidney and brain tissues were removed, chopped fine, washed and ground in a mortar and pestle with distilled water in a 1:2 dilution (grams wet tissue per milliliter water). In case of kidney and brain pooled tissue from several tadpoles was used. Hemogenate was centrifuged at 10,000 rpm for 30 minutes and the supernatant so obtained was mixed with 40% sucrose in 1:1 ratio and 0.1 ml applied directly on the separation gel prepared according to Davis<sup>6</sup>. For first 5 minutes 2.5 m Amp. current per tube was applied which was then increased to 5 m Amp. and run carried for 20 minutes at 4° C. After electrophoresis gels were stained for esterase activity<sup>7</sup> and photographs made.

#### ESTERASE PATTERNS DURING METAMORPHOSIS OF TADPOLE TO ADULT *RANA TIGRINA*

SEVERAL biochemical changes underlie the process of metamorphosis from tadpole to an adult frog. Most studies have demonstrated quantitative changes in enzyme activities during this process<sup>1</sup>. However a notable qualitative variation is found in the tadpole and adult hemoglobins<sup>2</sup>. Recent studies on isozymes have shown altered patterns during development stages indicating a differential gene activity as the basis of development and differentiation<sup>3-5</sup>. In this study using disc electrophoretic technique we report changing esterase patterns during the metamorphosis of tadpole to adult *Rana tigrina*.

Large tadpoles of *R. tigrina* were collected from ponds around Warangal city. These consisted of

FIG. 1. Disc electrophoretic pattern of esterases of liver tissue from *R. tigrina* tadpole without limbs (I), with fore limbs (II), with both fore and hind limbs (III) and adult frogs (IV).

Figure 1 shows esterase patterns obtained with  $\alpha$ -naphthylacetate as substrate from liver tissue of tadpoles of three developmental stages and the adult frog. The esterase bands from other tissues were faint and could not be identified properly. Where such faint bands could be seen it was evident that the band patterns were different from one another among the above four stages. The liver tissue gave the maximum number of seven to twelve esterase bands which were distinct and

whose identity could be traced from one stage to another. From these patterns it is evident that majority of the esterase bands are common in all stages. This identity is less apparent because of the extremely low intensity of some bands in some stages. However, in some stages there is an absence of certain bands. The absence of a band need not necessarily mean that such isozyme is not produced at all although such possibility cannot be ruled out. These zymograms then indicate that some esterase isozymes either are not produced in a particular stage of development or are produced in extremely low quantities. This study however shows that esterase isozymes vary from one stage of development to another and this might have a genetic basis in the activation of specific genes at particular stages as has been shown in other cases<sup>3</sup>. Such difference in esterase patterns were also observed in an electrophoretic study of *R. cates-biana*<sup>5</sup>. Our study confirms this observation and suggests the differential gene activity as the basis of development and differentiation.

#### ON THE MALFORMED CAUDAL NEURO-SECRETORY SYSTEM IN *CLARIAS* *BATRACHUS* L.

DURING the course of a comparative anatomical study on the caudal neurosecretory system in teleosts<sup>1</sup>, eleven specimens of *Clarias batrachus* were found to have aberrant tail. Although their caudal fin was normal in appearance, the caudal portion was tapering. This has promoted us to study the histomorphology of the caudal neurosecretory system in these specimens.

After fixing the caudal portion of the fish in Bouin's fluid for 24 hours and washing with 70% ethanol, the sample was dissected under a low power microscope. It is observed that the preterminal vertebra was irregular, appear knobby in shape and

is invaded by irregularly modified tissue of the spinal cord. The integument in the caudal extremity is closely connected with fibrous tissue. The spinal cord is distended dorsoventrally and is narrowed down gradually towards the caudal end.

A section of the spinal cord, prepared after histological technique<sup>2</sup>, shows wide central canal and dislocated urophysis (Fig. 1). The central canal becomes irregularly widened and contains hyaline cerebrospinal fluid. There is Reissner's fibre coiled up in the form of knots. The central canal is lined up with thick layer of ependymal cells from which processes emerge and end on the periphery of the spinal cord. The Dahlgren cells are concentrated in the attenuated portion of the caudal spinal cord. They are distributed dorsal to the urophysis. A few Dahlgren cells, which line a small isolated canal, are also seen at the extreme end of the spinal cord. The other elements present in this region are glia and ependymal cells.

The urophysis is a small, irregularly shaped region showing mostly medullary fibres and numerous capillaries. There are large Herring bodies as well as

FIGS. 1-2. Fig. 1. Sagittal section of the caudal spinal cord showing wide central canal (CC) and malformed urophysis (arrow). Dark outline around the central canal shows distribution of ependymal cells. Haemalum-eosine,  $\times 17$ . Fig. 2. Enlarged portion of the malformed urophysis showing several medullary fibres and Herring bodies (arrows) of various size. Haemalum-eosine,  $\times 270$ .

small sized droplets of the neurosecretory material (Fig. 2).

In normal specimens of *C. baruchas*, the caudal neurosecretory system has a narrow central canal; the enlarged ventral portion of the spinal cord called trophysis and a filum terminale. The Dohlgren cells are dorsally and are numerous in the region where the trophysis begins to bulge out.

The malformed caudal neurosecretory system is recorded only in *Anacilla japonica*. The occurrence of Dohlgren cells in a limited area of the caudal spinal cord and dislocated trophysis in *C. baruchas* is in agreement with the finding of Imai<sup>4</sup>, who regards them as products of regeneration. It is possible that the malformed nature of this system in *C. baruchas* is due to the regenerated portion of the tail which met with an accident in the nature. If it is so, the enlarged portion of the central canal would form an important route for discharge of secretory products in it and thus would serve as an important link in the functional efficiency of the system.

# NEW RECORD OF THE ROTIFER *TRIPLEUCHLANIS PLICATA* (LEVANDER) FROM INDIA

IN India, Eucharid rotifers are little known. Stewart<sup>1</sup> reported one species from Tibet, Edmondson and Hutchinson<sup>2</sup> six species from Punjab and Kashmir, Nayar and Nair<sup>3</sup> one species from Kerala and Dhanapathi<sup>4</sup> eight species including a new species from Andhra Pradesh. During limnological investigations three specimens of the rotifer *Tripleuchlanis plicata* were obtained from Municipal tank, Kalkalur (Krishna Dt., A.P.) during January 1974. The locality of collection was with dense growth of *Hydrilla*, diatom species of *Asterionella*, *Fragilaria*, *Gyrosigma*, and *Narvicula*, and green alga *Closterium*. The physico-chemical conditions of water at the time of collection were temperature 20°C, pH 7.4, dissolved oxygen 3.4 ml/L, carbonates 30 ppm, bi-carbonates 140 ppm. It is being reported for the first time from India.

**Description.**—*T. plicata* is ovoid. Dorsal plate of the lorica with emargination posteriorly and the ventral of same size as dorsal. Lateral longitudinal sulci are separated by cuticular flange giving bellows

effect laterally. Mastax malleate type, with overlapping teeth in each uncus. Foot glands long including a pair of accessories. Foot three jointed, projects beyond the lorica; first foot joint covered by small cuticular plate. Toes short and parallel (Fig. 1). Measurements: length of the body 165 µ, of dorsal plate 84 µ, of ventral plate 98 µ, and of toes 28 µ.

FIG. 1. *T. plicata*, dorsal view.

**Discussion.**—Myers<sup>5</sup> stated that "*T. plicata* is common in the salt water of bays and inlets, wherever there is growth of marine algae; it is the only marine Eucharid rotifer known". Rodewald<sup>7</sup> described *T. plicata* var. *razelmi* from brackish waters of Rumania, with long and narrow lorica, deep rounded cut for dorsal plate and longer cuticular plate on the foot than *T. plicata*. Anne Thane-Fenchel<sup>8</sup> reported it from marine waters of Denmark. Dr. P. J. Donner, Austria, stated (personal communication) that he has obtained it from a freshwater reservoir in Madras.

It was not found in my earlier collections from several districts in Andhra Pradesh, Ootacamund (Tamil Nadu), and Ranchi (Bihar). I consider occurrence of *T. plicata* in freshwater as very rare but, more detailed study is required to know about its distribution.

Thanks are due to Dr. P. J. Donner (Austria) for his suggestions. Thanks are also due to Sri. S. Rama Rao, Head of the Department of Zoology and Sri. P. Srirama Murty, Senior Lecturer in Chemistry, D.N.R. College, Bhimavaram, for

providing the necessary facilities to carry out the work.

#### NATURAL OCCURRENCE OF BACTERIAL LEAF STREAK DISEASE OF RICE ON *ORYZA PERENNIS*

BACTERIAL leaf streak disease of rice (*Oryza sativa*), caused by *Xanthomonas translucens* f. sp. *oryzicola* (Fang et al.), Bradbury, is widely distributed in tropical Asia. Under favourable weather conditions, the disease spreads in a severe form and causes as much damage as bacterial leaf blight<sup>1</sup>. The role of seed transmission in the perpetuation of the disease has been shown<sup>2</sup>, however, the part played by the weeds in transmitting the disease is little understood. The stagnant water in marshy ponds and streams located in the vicinity of rice fields support the growth of a perennial wild rice, *Oryza perennis*, which is distributed widely in Uttar Pradesh, Madhya Pradesh, Bihar, West Bengal, Orissa, and Andhra Pradesh<sup>1</sup> which form the major part of the rice belt in India. The role of *O. perennis* as an alternative host in the epidemiology of this disease is investigated.

In the beginning of the wet season during the year 1973 before the paddy crop was transplanted in the fields, it was observed that the leaves of *O. perennis* exhibited severe symptoms of streak disease similar to that on rice plants under natural conditions in and around Cuttack, Orissa State. In course of time, the transplanted paddy crop nearby was also severely diseased.

Diseased leaf tissues of *O. perennis* when placed in water exhibited typical bacterial oozing from the cut ends. The bacterium was isolated on potato-sucrose-agar medium and identified as *Xanthomonas*. Fifteen different wild rice species including the natural host of this isolate, *O. perennis* and one month old rice (*O. sativa*) cultivar, T(N)1, raised in pots were artificially inoculated by swabbing the bacterial suspension with muslin cloth obtained

from 48 hr old culture on potato-sucrose-agar medium<sup>3</sup>. Inoculated plants were kept in the open at  $30 \pm 2^\circ\text{C}$ .

Typical water soaked, translucent, interveinal streaks appeared on the leaves of *O. perennis* and the rice cultivar, T(N)1, four days after inoculation and subsequently in a few days they turned reddish brown. The bacterium re-isolated from the infected leaves of cultivar, T(N)1, brought about typical disease symptoms on *O. perennis*, four days after inoculation. Six of the wild species, i.e., *O. barthii*, *O. latifolia*, *O. officinalis*, *O. malampuzhensis*, *O. glaberrima* exhibited susceptible reaction, while *O. grandiglumis*, *O. punctata*, *O. alta* and *O. australiensis* showed resistant reaction. However *O. eichingeri*, *O. granulata*, *O. ridleyi*, and *O. brachyantha* did not exhibit any symptom.

Seeds harvested from naturally infected field with bacterial leaf streak<sup>2</sup> and from artificially inoculated plants<sup>7</sup> were found to carry the inoculum from one season to the other. A few wild rice species including *O. perennis* were found to be susceptible to this disease under artificial inoculation tests at the International Rice Research Institute, the Philippines<sup>3,4</sup>. The natural occurrence of this disease on *O. perennis* and the ease with which it passes to cultivated rice and from rice back to the wild rice suggests that *O. perennis* may act as an alternative host and play a role in the epidemiology of the disease.

Deep appreciation is extended to Dr. S. Y. Padmanabhan, Director and Dr. N. K. Chakrabarti, Head, Division of Plant Pathology, for their encouragement and for providing facilities. Thanks are also due to Mr. P. J. Jachuck for supplying the wild rices and to Dr. R. Sridhar for critically going through the manuscript.

# EMBRYOLOGICAL STUDIES IN *RICHARDIA SCABRA* LINN.

RECENT contributions to the embryology of the family include those of Fagerlind (1937), Shivaramaiah and Sundara Rajan (1973).

The material for the present work was collected round about Bangalore. The flower buds were fixed in F.A.A. and the usual embryological procedure was followed.

*Richardia scabra*, Linn. belongs to the tribe Spermacoceae.

A transection of an young anther lobe shows an epidermis, an endothecium, a middle layer, a tapetum and one microspore mother cell (Fig. 1). The tapetal cells are uninucleate throughout and are of glandular type. Endothecium exhibits fibrillar thickenings at the time of anther dehiscence (Fig. 2). Microspore mother cells undergo reduction division to form tetrahedral tetrads of microspores (Fig. 3). Mature pollen grain has a thick exine with glandular projections and a thin intine. It is shed at the 2 celled stage (Fig. 4).

FIGS. 1-13. Fig. 1. T.s. of anther lobe.  $\times 300$ . Fig. 2. Fibrillar endothecium,  $\times 300$ . Fig. 3. Microspore tetrad,  $\times 700$ . Fig. 4. 2-celled pollen grain,  $\times 300$ . Fig. 5. Archesporial cell. Figs. 6 and 7. Tetrads of megaspores.  $\times 300$ . Figs. 8-10. Development of embryosac.  $\times 300$ . Figs. 11-13. Free nuclear endosperm and zygote.  $\times 300$ .

The ovary is inferior with pendulous ovules. The nucellus is highly rudimentary. At the

archesporial cell stage it is represented by a single cell. Even this degenerates at the megaspore mother cell stage. The nucellus is of the *Hautontia* type (Fagerlind, 1937). A single hypodermal archesporial cell is differentiated and it directly functions as the megaspore mother cell (Fig. 5). The megaspore mother cell undergoes reduction division to give rise to generally a linear tetrad of megaspores. Occasionally juxtaposed twin tetrads are also noticed (Figs. 6 and 7). Of the four megaspores the chalazal alone is functional. The functional megaspore gives rise to an 8 nucleate embryosac of the *Polygonum* type (Figs. 8-10). In spite of the presence of twin tetrads no twin embryosacs have been observed. The organised embryosac is 7 nucleate with an egg apparatus having beaked synergid and a median egg.

Fertilisation is porogamous. The endosperm development is free nuclear (Figs. 11-13). The zygote remains quiescent for a long time until about 200 endosperm nuclei are formed.

Our thanks are due to the Principal and Head of the Department of Botany, St. Joseph's College, Bangalore, for facilities.

## ON FOLIAR TERMINAL VESICULOSE SCLEREIDS IN *GOUPIA GLABRA* AUBL.

IN the course of a thorough systematic reinvestigation on the several foliar sclereid bearing taxa mentioned in the works of Solereder<sup>1</sup>, and Metcalfe and Chalk<sup>2</sup> the writers came across an interesting occurrence of terminal vesiculose sclereids previously not reported in the leaf expanses of *Goupia glabra*, an aberrant taxon from Amazon, British Guiana and Columbia. This feature is studied in detail in view of the progressive systematic status of this taxon into a separate family, Goupiaceae.

### MATERIALS

*Goupia glabra* Aubl. South America, Amazon, Basin of Rio Madera, B. A. Krukoff 5943 (LE); Amazon, Juijirimom Bandel, Richard Evans Schultes et Isidoro Cabrera 149504 (LE); British Guiana, Near Bartica, N.Y. Sandwith 379 (LE).

A perusal of the literature has revealed that but for a succinct statement that 'mesophyll composed of two layers of palisade tissue, and a broader spongy region, containing branched sclerenchymatous elements' (Metcalfe and Chalk)<sup>2</sup> there is no detail

information available on the types of sclereids encountered in the leaf expanses of this taxon. It is evident from the above statement in agreement with Foster<sup>3</sup> that earlier workers have not employed the clearing technique with advantage to know the overall pattern of sclereid distribution and the relationship with vein-endings.

FIGS. 1-3. Fig. 1. Surface view of vesiculose sclereids at the vein-endings and also vermiform sclereids closely adpressed to the minor veins,  $\times 60$ . Fig. 2. Veinlet-ending with a single vesiculose sclereid,  $\times 60$ . Fig. 3. Transection of the leaf showing vesiculose sclereids in the spongy tissue,  $\times 60$ .

The interesting feature of the present study of cleared leaves, transverse and paradermal sections is the discovery of terminal vesiculose sclereids at the vein-endings. Its terminal disposition is relatively constant and this pattern seems to be constant in almost all the cleared leaves. The sclereids

conform to vesiculose type *sensu* Rao and Bhupal<sup>4</sup>. In cletred lamina they are parallelly oriented to the surface of the lamina and possess birefringent thin walls with wide lumina without any contents. This type varies from sub-spherical to irregularly lobed form, but invariably sac-like at the vein-endings (Figs. 1, 2). Frequently, they appear in groups of 2 to 4 in close juxtaposition. Infrequently, single large sac-like sclereid is found at the vein-ends, almost enclosing the terminal portion of the veinlet (Fig. 2). In transections they are disposed in the broad spongy region in groups of two to three (Fig. 3). In size they are larger than the surrounding spongy cells and irregularly oriented around vascular bundles. Further, it is evident from an analysis of venation pattern of the cleared leaves that the midrib and the other major veins possess compact sclerenchymatous sheaths, whereas the minor veins have less sclerenchyma but only a few scattered isolated sclereids with round wall endings (Fig. 1) apparently resembling the vermiform type of sclereid. These sclereids are distinct from the vesiculose sclereids in their specific topographical disposition and orientation along the veins. They have thick cell walls with conspicuous pits and narrow lumen. Infrequently, they are found intruding into the mesophyll.

This taxon is incorporated in Celastraceae in Bentham and Hooker System. Losner<sup>5</sup> erected for this aberrant taxon a sub-family Goupioideae within the Celastraceae. Miers<sup>6</sup> recommended raising this taxon to distinct family level, Goupiaaceae. According to Dr. T. A. Spraguel (quoted by Metcalfe and Chalk)<sup>1</sup> this taxon has sufficient distinct characters to exclude from the Celastraceae. Recent researches have shown undoubtedly that the occurrence of foliar sclereids in many phanerogams are of obvious positive taxonomic significance. The present finding of terminal vesiculose sclereids at the vein-endings will certainly be a helpful diagnostic character with other distinct characters mentioned before<sup>1</sup> to accommodate this genus into a family in its own right.

The senior author is grateful to the authorities of the Academy of Sciences of U.S.S.R., the Department of Science and Technology and the Director of Botanical Survey of India for providing him the opportunity of visiting U.S.S.R. under Indo-Soviet Scientific and Cultural Exchange programme during 1973-74. Furthermore, he is grateful to the authorities of V. L. Kumarov, Botanical Institute, Leningrad, for the gift of leaf-specimens of several sclereid bearing taxa of flowering plants.

### ON THE OCCURRENCE OF NATURAL HYBRIDIZATION BETWEEN *SOLANUM INCANUM* LINN. AND *SOLANUM MELONGENA* LINN.

EXPERIMENTAL hybrids between *Solanum incanum* and *Solanum melongena* have been well established, Bhaduri (1951)<sup>1</sup>; Zutshi (1968)<sup>2</sup>.

While on a collection trip to the Cheruma tribe in search of primitive cultivars of economic plants of Kerala an extremely spinous form of *Solanum incanum* with small green fruits was found growing on the roadside near Shoranur.

Fruits of this plant were collected and seeds sown in the Ethnobotanical Garden of the Field Research Laboratory, University of Madras. Amongst the seedlings raised which were similar to the plant collected (Fig. 1), one plant stood out by its vigorous growth, large pubescent leaves and rudimentary spines. This aberrant seedling had larger flowers, and fruits which were purple in colour, a character not so far seen in *Solanum incanum* (Fig. 2).

FIGS. 1-3. Fig. 1. A normal *Solanum incanum*, Linn. plant. Fig. 2. The aberrant plant. Fig. 3. Segregation for fruit size and colour from the aberrant plant.

Selfed seedlings of this aberrant plant showed segregation for colour and size of fruits—the largest

fruit resembling a round *Solanum melongena* and the smallest similar to *Solanum incanum* parent. The different types of fruits present in the segregating generation are illustrated in Fig. 3. We can thus infer that hybridization between *Solanum incanum* and *Solanum melongena* occurs in nature.

Some of the forms of the segregates correspond to the description by Hooker (1885)<sup>3</sup> for *Solanum coagulans*. The hybrid nature of *Solanum coagulans* and the possibility of its being a primitive cultivar of *Solanum melongena* is thus indicated by this study.

I wish to thank Dr. E. K. Janaki Ammal for her guidance in this study, which is part of the project "Ethnobotanical studies of South Indian aboriginal tribes" financed by the Indian National Science Academy.

### THE NATURE OF PECTIC ENZYMES PRODUCED BY *PHYTOPHTHORA PARASITICA* VAR. *SESAMI* IN TWO CULTURE MEDIA

*Phytophthora* blight is causing serious damage to sesamum crop in Rajasthan (Prasad *et al.*, 1966). The disease has earlier been reported from Gujarat (Kale and Prasad, 1957). In Rajasthan the disease was severe in 1973 around Udaipur. Isolations from diseased tissues yielded pure cultures of the pathogen. This is a preliminary report on work in progress in our laboratory on the host-parasite relations of this disease.

The pathogen was grown on potato pectin medium (Talboys and Busch, 1970) and Asthana and Hawker's medium (Dube, 1971) with pectin as the carbon source. Culture filtrates were assayed for pectic enzyme production by the pathogen after seven days. The identification of hydrolytic or *trans*-eliminative cleavage of the pectic substances was made spectrophotometrically by Thiobarbituric acid test of Neukom (1960), as modified by Sherwood (1966). Spekolsingle beam spectrophotometer was used for the purpose of determining the absorption spectrum over the range of 480-580 nm. Occurrence of a

peak at 510 nm indicated hydrolytic cleavage by a polygalacturonase and a peak at 547-550 nm was evidence for a *trans*-eliminative split and therefore for pectin lyase.

Seven days old culture filtrate of the fungus growing on potato-pectin medium when assayed showed maximum absorption at 510 nm (Fig. 1). This peak at 510 nm occurred at a pH range of 5 to 8; there was no activity below pH 5 and above 8. The pH for maximum enzyme activity was found to be 6. There were peaks showing enzyme activity on both sodium polypectate and pectin with similar effect of pH on the reaction mixture. There was no peak at any pH on 547 or 550 nm indicating absence of pectin-lyase.

FIG. 1. Absorption spectrum showing hydrolytic cleavage of NaPP at pH 6.

On Asthana and Hawker's medium, the culture filtrate, after seven days of fungal growth, showed the presence of a pectin lyase (Fig. 2). Distinct peak at 550 nm occurred at pH ranging between 5 to 8, though at pH 5 the peak was highest.

This evidenced the presence of a pectin lyase. Here too, the enzyme activity occurred on both the substrates, viz., sodium polypectate and pectin though the pH for maximum enzyme activity did vary in the two cases. On pectin the highest peak was recorded at pH 6.

FIG. 2. Shows *trans*-eliminative cleavage of pectin at pH 5.

The results are interesting on two scores: (i) the culture conditions, viz., the nature of growth medium, determined the nature of the enzyme production by the pathogen and, (ii) the pH for maximum activity was in the acidic range, for the pectin lyases are usually reported to be active in the alkaline range.

Grateful thanks are due to Professor Y. D. Tiagi for providing laboratory facilities and for critically reading the manuscript.

# MORPHOGENESIS IN EMBRYONAL CALLUS OF *EUPHORBIA PULCHERRIMA* IN VITRO

REPORTS on the *in vitro* morphogenesis of embryo and the induction of polyembryony are available<sup>1,2</sup>. In *Euphorbia pulcherrima* the induction of the hypocotyledonary buds in seed cultures was earlier described<sup>3</sup>. This communication deals with the embryo proliferation and its subsequent differentiation into embryoids and plantlets.

Mature seeds of *Euphorbia pulcherrima*, an ornamental plant, were collected and the seed coat removed. Following the aseptic technique, the decoated seeds were cultured on a modified Whites' medium without IAA<sup>4</sup>, containing 2% sucrose (BM) and also on BM with supplements like coconut milk (CM), IAA, GA<sub>3</sub>, kinetin and casein hydrolysate (CH) either individually or in different combinations. The cultures were maintained under controlled conditions of temperature, light and humidity.

On BM and BM + CM (10%), the seeds showed upto 90% germination but callusing was not noted. But on all the other nutrient media tried callus formation was observed and the percentage of cultures showing seed germination, differentiation of hypocotyledonary buds and callus are summarised in Table I. On BM + kinetin (1 ppm) only 5% and

TABLE I

Percentage of cultures showing seed germination, shoot buds and callus

| Nutrient media                             | Germination | Shoot Buds | Callus |

| BM   | 90          | 35         | ..     |
| BM + CM (10%)                              | 90          | 35         | ..     |
| BM + IAA (1 ppm)                           | 70          | 35         | 10     |
| BM + IAA (1 ppm)<br>+ CM (10%)             | 50          | 35         | 10     |
| BM + kinetin (1 ppm)                       | 70          | 20         | 5      |
| BM + kinetin (1 ppm)<br>+ CM (10%)         | 35          | 25         | 15     |
| BM + GA <sub>3</sub> (1 ppm)               | 70          | ..         | ..     |
| BM + GA <sub>3</sub> (1 ppm)<br>+ CM (10%) | 65          | 10         | 10     |
| BM + 2, 4-D (1 ppm)                        | ..          | ..         | ..     |
| BM + 2, 4-D (1 ppm)<br>+ CM (10%)          | 25          | 8          | 35     |

Growth period : 10 weeks. Average of 24 cultures.

on BM + kinetin (5 ppm) + CH (500 ppm); BM + kinetin (5 ppm) + 2, 4-D (2 ppm); BM + kinetin (5 ppm) + 2, 4-D (2 ppm) + CH (500 ppm); BM + kinetin (1 ppm) + IAA (1 ppm) + CH (500 ppm) and BM + 2, 4-D (2 ppm) + CH (500 ppm) all the cultures produced callus.

The seeds within 3 days of culture enlarged rapidly followed by the emergence of radicle. The latter swelled considerably and the hypocotyl region proliferated (Fig. 1) profusely yielding a mass of yellowish-brown, fleshy callus after 2 weeks of culture. In a few cultures that the callusing was so profuse the entire seed lost its identity within the fast growing callus.

Interestingly, in about 6 weeks numerous embryoids invariably differentiated in the callus (Figs. 2, 3). These embryoids were pale-yellow and developed into plantlets (Fig. 4). The development of these embryoids was not synchronous and several embryoids at different stages of their ontogeny were seen intimately mixed with the mature ones. The callus was subculturable and continued to differentiate embryoids.

FIGS. 1-6. Fig. 1. Seeds grown on BM + CH (500 ppm) + 2, 4-D (2 ppm) showing the formation of callus. Fig. 2. A 6-week-old culture on BM + kinetin (5 ppm) + CH (500 ppm) with a mass of callus and proembryoids. Figs. 3, 4. Embryoids and plantlets. Fig. 5. L.s. of a seed after a week in culture to show the origin of callus; note the proliferated hypocotyl. Fig. 6. A portion of callus in section passing through a proembryoid.

Histological preparations of the callusing seeds revealed that the cotyledons and the shoot apex remained unaffected and the callus originated from

the entire hypocotyl region (Fig. 5). The actively growing callus contained parenchymatous cells of diverse sizes and shape. The cells were largely uninucleate, densely cytoplasmic and were studded with starch grains. Occasionally binucleate cells were also noted.

The embryoids originating from the callus elongated considerably along the radicle-plumule axis, but the differentiation of cotyledons was very poor. The radicle penetrated into the medium and organized into a primary root with a prominent root cap. Anatomically the callus comprised several proembryoids (Fig. 6) which were easily recognised by their typical organization. In several cultures the endosperm also exhibited rapid proliferation yielding a mass of tissue capable of differentiation. Further studies on endosperm morphogenesis are in progress.

I am indebted to Professor M. S. Chennaveeraiah for his help and encouragement.

#### **SCHIZOTETRANYCHUS ANDROPOGONI (HIRST) (ACARINA: TETRANYCHIDAE) A NEW RECORD OF PADDY PEST IN INDIA**

PADDY has so far been reported to be attacked in India only by one species of mite, i.e., *Oligonychus oryzae* (Hirst<sup>1</sup>). Recently, a thorough survey of paddy crop at Chinsurah, Kalyani and Krishnanagar areas of West Bengal revealed the existence of another mite, *Schizotetranychus andropogoni* (Hirst) which infested several varieties of paddy in pest form and did considerable damage to crop during August–September 1972. Earlier, this mite has been reported as pest on sugarcane (*Saccharum officinarum*<sup>2-3</sup>), on *Dicanthium annulatum*<sup>4-5</sup> and *Saccharum spontaneum*<sup>6-7</sup>.

This mite was in small colonies mostly on the under-surface of leaves but when the infestation was severe, its occurrence on upper surface of leaves was also quite common. These mites cause whitish patches in rows arranged irregularly on either sides of midrib. All the patches remain covered with thin webs where the mite colonies lived. Paddy fields having serious injuries of mites looked sickly and turned yellowish.

Sixteen varieties of paddy were examined in the field for their relative susceptibility to the attack of *S. andropogoni*. Population of mite was highest on NC 918 (460) and lowest on Satika (20). IR 8 was completely free from mite attack. The population of mite was heavy during August–September, gradually dwindled during October and became nil during end of November.

TABLE I

| Sl. No. | Name of variety          | Population per 10 leaves |
|---------|--------------------------|--------------------------|
| 1       | NC 918                   | 460                      |

| 15      | Satika                   | 20                       |
| 16      | IR 8                     | 0                        |

Two species of *Oligonychus*, viz., *O. indicus* (Hirst) and *Oligonychus* sp. were associated but their population were insignificant. Two species of predatory phytoseiid mites, viz., *Amblyseius fallacis* (Garman) and *A. longispinosus* (Evans) and one species of Tydeidae, viz., *Pronematus* sp. were abundantly found on all the varieties of paddy and found very efficiently feeding on the eggs of *S. andropogoni*. One species of Acaridae were also found to occur on paddy but its role could not be ascertained.

The author is grateful to Dr. A. P. Kapur, Director, for the facilities. Thanks are also due to the authorities of the Agricultural farms for the permission to record observations.

## SHORT SCIENTIFIC NOTES

**New Records of Alternate Hosts of Tobacco Caterpillar, *Spodoptera litura* Fab. (Noctuidae: Lepidoptera. and Bihar Hairy Caterpillar, *Diacrisia obliqua* Wlk.) (Arctiidae: Lepidoptera)\***

Tobacco caterpillar, a polyphagous pest which had been reported to attack about 103 host plants<sup>1,2</sup>, was found damaging gladiolus by feeding on the flowers extensively at the experimental farm, Hessaraghatta, of the Indian Institute of Horticultural Research. A spray of 0.05% paration emulsion could effectively control the pest.

Bihar hairy caterpillar, a similiar polyphagous pest with over 40 host plants<sup>3,4</sup>, caused severe damage to the globe artichoke (*Cyanara scolymus*) by feeding on the leaves. These alternate hosts of both the pests are placed on record for the first time.

Thanks are due to Dr. G. S. Randhawa, Director, Indian Institute of Horticultural Research, Bangalore, for encouragement.

**First Record of a Host for the Chalcid Parasite *Brachymeria croceogastralis* Joseph *et al.***

During the course of rearing of *Perina nuda* Fabr. (Lepidoptera : Lymantriidae) which fed on the leaves of fig trees in our college orchard in October 1960, a number of chalcids emerged from the pupae in the laboratory. The parasites were identified as *Brachymeria croceogastralis* Joseph *et al.* (Chalcididae). Joseph *et al.*<sup>2</sup> have described the species from specimens collected at Bangalore (India) from unidentified pupa but no specific host of the parasite has been reported. The parasite complex mentioned by Cherian and

Israel<sup>1</sup> does not include *B. croceogastralis* and as such forms a first record.

Thanks are due to Prof. K. J. Joseph for having identified the parasite and to Prof. T. R. Subramaniam for the facilities provided.

**Leaf Margin Roll Gall on *Ficus tomentosa* Roxb. Caused by a Psyllid *Mycopsylla gardenensis* Bhanotor (Hemiptera)**

The psyllid, *Mycopsylla gardenensis* Bhanotor has been observed for the first time to cause leaf margin roll gall on *Ficus tomentosa* Roxb. in and around Madurai region. Feeding by the psyllids results in a typical phytotoxemia of primary tissue malformation on the leaves. The apex of the leaf is rolled and folded back on the underside upto half way of the leaf blade and/or leaf margins on the lateral sides are sharply folded and fixed on the lower side. The entire blade becomes rolled, crinkled and spirally twisted into a tubular structure in young leaves. The rolling of the blade is almost accompanied by swelling, crinkling and curling.

Groups of greenish flattened nymphs remain feeding inside the leaf rolls in a cottony cushion. Whitish waxen threads project from the extremity of abdomen giving an appearance of masses of cotton to the nymphal aggregation. Adults disperse throughout the branches. Honey dew, secreted copiously by the nymphs, drops downwards and attracts several flies and wasps.

A pit gall caused by *Trioza* sp. on *Ficus religiosa* L. and a pouch gall on *Ficus glomerata* Roxb. by *Pauropsylla depressa* Crawford, have been reported from India<sup>2</sup>. Trotter<sup>3</sup> has observed a leaf margin roll gall on *Ficus nervosa* Heyne<sup>1</sup>, caused by an unknown psyllid from Formosa. This is the first record of leaf margin roll gall on *Ficus tomentosa* Roxb. caused by a psyllid.

The authors are thankful to Dr. D. Hollis, British Museum (Natural History), London, for having kindly identified the psyllids.

#### *Achlya stellata* de Bary—A New Record from India

*Achlya stellata* has been recently isolated from a water sample from Gorakhpur which forms the first record of this fungus from India. The following description of the isolate is made from bacteria-free cultures growing on sterilized hemp-seed halves in sterile distilled water at 22–25° C.

#### *Achlya stellata* de Bary

*Mycelium* moderately extensive, diffuse; two-week-old colony 1.5–2.5 cm in diameter; principal hyphae slender, branched, 70–105  $\mu$  in diameter at base. *Zoosporangia* moderately abundant fusiform or clavate, less frequently naviculate or filiform; 275–550  $\mu$  long by 18–45  $\mu$  in diameter, predominantly 350–500  $\times$  25–35  $\mu$ ; renewed sympodially, occasionally cymosely; zoospore discharge achlyoid; spore cluster not persistent; encysted spores 7.3–10  $\mu$  in diameter. *Gemmae* absent. *Oogonia* abundant, terminal on main hyphae or on lateral branches which are commonly curved or rarely once coiled; oogonia spherical pyriform, often with a neck, the basal septum often having an inward projection; 35–84  $\mu$  in diameter predominantly 55.5–70  $\mu$  inclusive of ornamentations. Oogonial wall unpitted; densely ornamented with conical or mammiform papillae. *Antheridia* usually absent or very sparse—present on about 1% oogonia; when present normally one to an oogonium; monoclinal (androgynous) on a long or rarely short antheridial branch, antheridial cells thin walled, tubular or clavate; apically or very rarely laterally appressed to the oogonium. *Oospheres* usually one, rarely two in an oogonium, normally, spherical but occasionally ovoid, filling the oogonium and maturing. *Oospores* subcentric; 32.5–46.5  $\mu$  in diameter, predominantly 30–37  $\mu$ .

Collected from Jalwania Pond, Gorakhpur, January 12, 1974. I wish to thank Dr. M. W. Dick, University of Reading, England, for critically examining the description and offering valuable suggestions. I also wish to thank Dr. Y. B. Singh, Principal, St. Andrew's College, Gorakhpur, for providing facilities for work.

#### Axillary Testis in the Common House Crow (*Corvus splendens* Vieillot) and Cattle Egret (*Bubulcus ibis* Linnaeus)

While studying the annual reproductive cycle of some avian species inhabiting the semi-arid and arid tracts of Rajasthan one specimen each of the common house crow and egret was encountered which exhibited an axillary testis. Both the abnormal birds were examined in the month of July when the birds were sexually active.

In most of the birds including the crow and egret the left testis is longer than the right. However, in the abnormal birds the left testis was smaller than the right. The left axillary testis was attached independently and was in direct communication with the left vas deferens.

Histologically, the axillary testis of common house crow and cattle egret resembled in every respect with the individual testes of the abnormal specimens as well as with the testes of normal sexually active males dissected on the same day. The axillary testes of both the specimens were spermatogenetically active containing all stages of developing germ cells.

In the absence of earlier reports, the above abnormalities in the male reproductive organs of the common house crow and the cattle egret, may be considered to be purely developmental in which probably physiological rather than cytological or genetic changes are concerned.

## A Very Early Mutant in Rice

The early rice mutant reported here was obtained from the hybrid culture CR. 113-32 following gamma ray treatment (30 Kr from a 60 Co source) of dry seeds.

The mutant was 9 cm shorter in height, 18 days earlier in duration and 3 cm shorter in panicle length than the control. Another interesting change was in the shape of grain to short bold from medium slender. There was no other significant morphological change in the mutant. It was sown on 22nd June, 1974 and harvested on 28th August, i.e., a total growth period of 68 days. During this period, the rainfall at Cuttack was 492 mm.

Induction of earliness through mutation has been reported by many workers earlier. Recently Miah and Bhatti<sup>1</sup>, Saini and Gajenja<sup>2</sup>, Roy and Jana<sup>3</sup> and Miah *et al.*<sup>4</sup> have reported mutants which are 11-28 days earlier than controls. Simon<sup>5</sup> has reported mutants in rice which are 49 days earlier than its control. According to Yamagata<sup>6</sup>, mutations for heading time were more frequent than even chlorophyll mutations with gamma irradiation. In the present instance, the reduction in duration is eighteen days. This mutant was grown under completely upland condition on a sandy loam and gave 256 gm from 1.2 sq. meter or a computed yield of a little over 2 tonnes/ha. The duration (seed to seed) of this mutant in Cuttack was 80 days when transplanted in January, 68 days when direct seeded in June and 85 days when transplanted in September. This is possibly the earliest induced productive major cereal on record.

The authors thank Dr. S. Y. Padmanabhan, Director, Central Rice Research Institute, Cuttack, for facilities accorded.

## Isolation of Mycoplasmas from Pneumonic Lungs of Pigs in India

Goodwin *et al.*<sup>1</sup> and Mare and Switzer<sup>2</sup> isolated mycoplasma organisms in cell free medium from cases of enzootic pneumonia in pigs and called them as *M. suis* and *M. hyopneumoniae* respectively. The occurrence of mycoplasma in the Indian swine is reported for the first time.

The pneumonic and normal lung tissue from sick and healthy pigs were collected from a Bacon Factory where pneumonia of enzootic nature was reported<sup>3</sup>. The procedure of isolation of mycoplasma from these materials is given by Goodwin *et al.* From the eight pneumonic lungs, mycoplasma organisms were isolated on solid medium. The size of the colonies of mycoplasma on solid medium varied from about 20  $\mu$ -150  $\mu$  in diameter after incubating them for three days at 37°C in moist atmosphere, containing 5-10% CO<sub>2</sub> tension in 'Mc Intosh and Fildes' Jar. The small velvety colonies of mycoplasma were transparent having a characteristic 'fried egg' appearance and central elevation was not prominent in majority of them. The morphology and the growth characters of colonies were suggestive of *M. hyopneumoniae*. No mycoplasma could be isolated from six normal lungs.

Further studies on characterization of the different mycoplasma isolates and experimental reproduction of the disease are in progress. This is the first reported instance of isolation of mycoplasma from pneumonic lungs of pigs in India.

The authors thank the staff of C.D.F., Aligarh, for help in collection of the material and Principal Sri. C. V. G. Choudary for providing the facilities. Dept. of Bacteriology, U.P. College of Veterinary Science and Animal Husbandry, Mathura, December 25, 1973.

## REVIEWS AND NOTICES OF BOOKS

**Annual Review of Plant Physiology (Vol. 25).**  
Edited by Winslow R. Briggs, Paul B. Green and Russell L. Jones. (Annual Reviews, Inc., 4139, El Camino Way, Palo Alto, California 94306). 1974. Pp. 627. Price: U.S.A. \$ 12.00; Foreign \$ 12.50.

In this volume of *Annual Review of Plant Physiology* the following two review articles in the area of Cell organization in relation to function have appeared: (1) The  $C_4$  syndrome: A structural analysis by W. M. Laetsch and (2) Microtubules and microfilaments by P. K. Hepler and B. A. Palevitz. Under Nutrition, Absorption and Transport, one article on Uptake mechanisms (Inorganic and organic) by Per Nissen and another on Phloem transport Physical, Chemical or Impossible by I. F. Wardlaw are written. Two reviews one on: Metabolite exchange between chloroplasts and cytoplasm by U. Heber and another on Energy conservation in photosynthetic electron transport of chloroplasts by A. Trebst under Bioenergetics are included.

In the general topic of Metabolism the following five articles reviewing the different subjects are given: (1) Dinitrogen fixation by M. J. Dilworth, (2) Circadian rhythms and metabolic patterns by O. Queiroz, (3) Protein turn-over in plants and possible means of its regulation by R. C. Huffaker and L. W. Peterson, (4) The metabolism of aromatic compounds by H. A. Stafford, (5) Metabolism of auxin in higher plants by E. A. Schneider and F. Wightman.

In the field of development the five articles are: (1) Plant propagation through tissue culture by T. Murashige, (2) Control of seed germination by A. M. Mayer and Y. Shain, (3) Rapid responses to plant hormones by M. L. Evans, (4) Isozymes in development and differentiation by J. G. Scandalios, (5) The chemistry and physiology of abscisic acid by B. V. Milborrow are written.

Two special topics, Phytotoxins produced by Plant Parasites by G. A. Strobel and Physiology of Mycorrhiza by F. H. Mayer are reviewed.

The prefatory chapter of this volume by F. W. Went entitled "Reflections and speculations" makes an interesting reading. The rich experience of Dr. F. W. Went in the field of auxinology and plant environmental problems are very succinctly reported.

**Biology Digest.** Published by Data Courier, Inc., 620, South Fifth Street, Louisville, Kentucky 40202, U.S.A. Subscription \$ 75 per year, Vol. I, Issue 1, Pp. vii + 199. September 1974.

*Biology Digest* is a new monthly information service launched to organize, summarise and index worldwide scientific literature in the life sciences. The Digest is designed primarily to assist students and educators at the Secondary School and Undergraduate College levels in keeping current on latest scientific developments through abstracts and feature articles.

A subject of great topical interest 'What we know about cancers' is the feature article of this first issue. The Abstracts sections cover the areas of Plant life, Living systems, Micropopulations, Biosphere, Biogenesis and Development, Animal kingdom and Health science. M. SIRSI.

### ANNOUNCEMENTS

#### **Hari Om Ashram Vikram Sarabhai Research Awards for the Year 1974**

Hari Om Ashram Vikram Sarabhai Research Awards for the year 1974 have been awarded as follows:

I. Electronics and Telecommunications: Jointly to Dr. S. Krishnan, National Aeronautical Laboratory, Bangalore and Dr. S. Srikantan, Electronics Corporation of India, Hyderabad; II. Planetary and Space Sciences; Prof. Satya Prakash, Physical Research Laboratory, Ahmedabad; III. Atmospheric Physics and Hydrology: Dr. R. N. Keshavamurthy, Meteorological Department, Poona; IV. Systems Analysis and Management: Dr. N. Seshagiri, Electronics Commission, New Delhi.

#### **ĀRŌGYA—A JOURNAL OF HEALTH SCIENCES**

ĀRŌGYA—A Journal of Health Sciences (Half Yearly) will be published by The Academy of General Education under the Editorship of Prof. J. V. Bhat, Emeritus Scientist, Kasturba Medical College, Manipal. This Journal will disseminate authentic and reliable information on all aspects of Health Sciences as Medical, Dental, Pharmaceutical, Nursing and other Borderline areas as Bio-medical Engineering, Sociology, etc., etc.

Further details can be had from Prof. J. V. Bhat, Editor, ĀRŌGYA, Kasturba Medical College, Manipal 576119.

## INFORMATION TO CONTRIBUTORS

CURRENT SCIENCE is the Premier Science Fortnightly of India published by the Current Science Association, Bangalore and issued on the 5th and 20th of each month. All material intended for publication in CURRENT SCIENCE and books for review should be addressed to the Editor, *Current Science*, Raman Research Institute, Bangalore-560006.

The following types of Scientific Communications will be considered for publication :

- (i) Review articles on topics of major current interest not exceeding 4,000 words;
- (ii) Original Research Papers—not exceeding 2,000 words;
- (iii) Letters: These are brief reports of research of unusual and wide interest—they should not exceed 700 words in general;
- (iv) Short Scientific Notes—not exceeding 250 words.

Articles and papers should include a short abstract at the beginning.

References are indicated by superscripts in the text. The style of references should be *Journal*: The names of the authors, the journal, year, volume and page.

*Book*: Authors names, the title of the book, name and location of the publishers, year and page.

"Personal Communications" and "Unpublished Work" do not go into references and should be incorporated in the text. Acknowledgements should be brief.

Statements that the work is contribution No. .... of the Institute, declarations that the Director has authorised publications, etc., are not printed.

"Series" papers are discouraged.

Manuscripts, to be submitted in duplicate, should be typewritten in double space on one side of the paper, carefully revised and in final form for printing. Illustrations should be minimum in number, drawn in black and white with Indian ink on bristol board. Figures are usually reduced to one column width, and the originals should be about twice their final size.

No reprints are supplied gratis, but can be had on request at cost per V.P.P.

Business correspondence, remittances, subscriptions, advertisements, reprints, exchange journals, etc., should be addressed to the Manager, Current Science Association, Raman Research Institute, Bangalore-560006.

---

### Subscription Rates :

Institutions : India Rs. 84.00; Foreign Rs. 150.00; S 20.00 or £ 8.00.

Individuals : India Rs. 24.00; Foreign £ 3.50; \$ 8.00.

# ROLE OF $f$ -GRAVITY IN COSMOLOGICAL MODELS

C. SIVARAM, K. P. SINHA AND ERIC A. LORD

Division of Physics and Mathematical Sciences, Indian Institute of Science, Bangalore 560012, India

## ABSTRACT

The role of a massive scalar-tensor theory of  $f$ -gravity in cosmology is clarified to remove earlier ambiguities.

IN recent papers<sup>1,2</sup> we investigated the cosmological consequences of incorporating  $f$ -gravity (i.e., the short-range strong gravity field mediated by massive spin-2  $f$ -mesons with its coupling constant  $G_f$  of strength of the order of the strong interactions) together with a cosmological constant  $\Lambda_f$  of the order of magnitude of the square of the inverse Compton wavelength of the  $f$ -meson to take account of the short range. The purpose of the present note is to clarify a misleading ambiguity in that work, and to extend the discussion to cosmological models with spaces of non-zero curvature.

The Robertson-Walker (R-W) metric with flat 3-space ( $K=0$ ) is determined by the equation:

$$\dot{R}^2 = \frac{2GM}{R} + \frac{2}{3} \Lambda_f c^2 R^2 \quad (1)$$

where  $M = (4\pi/3) \rho R^3 = \text{total mass} = \text{a constant}$ . The  $\Lambda$ -term occurs with a positive sign, so that a *minimum* in the function  $R(t)$  will occur only if the coupling constant  $G_f$  of  $f$ -gravity that replaces the Newtonian constant (at short ranges) is *negative* and  $\Lambda_f$  *positive*. This was not made clear in references 1 and 2, because the  $\Lambda$ -term appeared with a negative sign.

The solution of equation (1) is:

$$R = (3 |G_f| M / \Lambda_f c^2)^{1/3} \cosh^{3/2} \left( t \sqrt{\frac{3 \Lambda_f c^2}{2}} \right) \quad (2)$$

This has a *minimum* at:

$$R_{\min} = (3 |G_f| M / \Lambda_f c^2)^{1/3} \quad (3)$$

With  $M$  being the total mass of the presently observable universe corresponding to  $\sim 10^{80}$  baryons. Using  $G_f$  as given in reference 3 and  $\Lambda_f$  as given in reference 4, we obtain:

$$R_{\min} \sim 10^{13} \text{ cm},$$

corresponding to a maximum density of

$$\rho_{\max} \sim \Lambda_f c^2 / 4\pi |G_f| \sim 10^{17} \text{ g.cm}^{-3},$$

as stated in references 1 and 2.

For  $K = \pm 1$ , the R-W line-element implies (i.e., for a curved 3-space):

$$\dot{R}^2 = \frac{2GM}{R} + \frac{2 \Lambda c^2 R^2}{3} \mp c^2 \quad (4)$$

For  $K = +1$ , and  $0 < \Lambda < C^2/3GM$ , the cosmology has no singularity anyway, so the question of invoking  $f$ -gravity does not arise. If the inequality concerning  $\Lambda$  is not satisfied, or if  $K = -1$ , we have to explore the possibility that the singularity is averted by the effects of  $f$ -gravity coming into play at high densities. Replacing the Newtonian  $G$

by  $G_f$  (negative) and  $\Lambda$  by  $\Lambda_f$ , we find a minimum value of  $R$  at

$$\begin{aligned} \sqrt{\frac{2}{\Lambda_f}} \cosh \left( \frac{1}{3} \cosh^{-1} A \right), & \quad (K = +1) \\ \sqrt{\frac{2}{\Lambda_f}} \sinh \left( \frac{1}{3} \sinh^{-1} A \right), & \quad (K = -1) \end{aligned} \quad (5)$$

where

$$A = 3 |G_f| M \sqrt{2 \Lambda_f} / c^2 \sim 10^{81} \quad (6)$$

As  $A$  is large, both the expressions (5) are approximately equal to the expression (3) for  $R_{\min}$ . Hence the maximum density is the same as for the case  $K=0$ . We emphasize that with negative  $G_f$  the  $\Lambda_f$  term is *essential* if  $K=0$  or  $+1$ , since with  $\Lambda_f=0$ , these equations have no real solutions.

The sign of  $G$  in general relativity is fixed by requiring that Newton's gravitational theory shall correspond to the linearised theory. However, to avert the singularity by incorporating  $f$ -gravity requires a repulsive short-range force, i.e., opposite sign of  $G_f$ . This naturally leads to the question as to how a theory with the repulsive effect necessary to avoid the cosmological singularity is consistent with recent work by two of the present authors (C. S. and K. P. S.) wherein  $f$ -gravity can also provide the strong binding forces for elementary particles. An answer to this is to be found in a recent paper of the authors in which the field equations of the short range massive  $f$ -gravity (with "cosmological" constant  $\Lambda_f$ ) is shown to give rise to a massive scalar-tensor theory. The ratio of the masses of the mediating particles is  $m_0$  (scalar)/ $m_2$  (tensor)  $= \sqrt{3}$ , indicating that the scalar has a shorter range. Furthermore, the tensor is found to be attractive (as in ordinary general relativity) whereas the scalar is a repulsive potential dominating at still shorter distances and higher densities. It is this repulsive interaction which averts the cosmological collapse. Under such conditions of high densities the weak Newtonian gravity (which is always attractive) loses its meaning.

## SUPERCONTINENTS OVER THE GEOLOGICAL TIMES

P. C. PAUL

*Geological Department, Bangalore University, Bangalore 560 075, India*

## ABSTRACT

A palaeomagnetic polar wander curve relative to India is prepared for the past 1600–1800 m.y. period. Comparison of this and the corresponding African curve suggests that Gondwanaland existed only about 100 m.y. ago. The palaeomagnetic data thus suggest that the history of the global surface since the middle Tertiary times has been characterised by the existence of three supercontinents during different periods—the Afro-American supercontinent from about 1800 m.y. ago, Gondwanaland from late Proterozoic till late Mesozoic, and the Eurasian supercontinent since the Tertiary times.

## 1. INTRODUCTION

ONCE crucial question in the postulate of global plate tectonics<sup>1,2</sup> is whether the large scale plate motions, known to have occurred since the late Mesozoic, also took place in the older times. The palaeomagnetic evidence strongly supports this possibility<sup>3,4</sup>. The palaeomagnetic data from Africa and the South and North Americas, for instance, suggest that these three continents were joined together in a single supercontinent until about 1600 m.y. ago<sup>5</sup>. Since the European data seem to contradict the existence of Pangaea in the Precambrian times, the question now arises whether this Afro-American assembly existed as part of a 'Greater Gondwanaland' or as a separate supercontinent. This is examined here from the palaeomagnetic data for the entire Proterozoic-Proterozoic interval which are now available for India, summarised below, Australia<sup>6,7</sup>, Africa<sup>8,9</sup> and South America<sup>4</sup>.

## 2. THE BIRTH OF GONDWANALAND

The palaeomagnetic poles obtained from the Indian rock formations are summarised in Table I and the corresponding polar wander curve is shown in Fig. 1. The Precambrian part of this is the modification of an earlier<sup>10</sup> polar wander curve and all the available data have been included. The Phanerozoic part of this curve is based on an earlier summary<sup>10</sup> and incorporates the new data<sup>11</sup> available since then. In view of the detailed magneto-stratigraphic correlations<sup>12,13</sup> and agreement with the marine-magnetic<sup>14</sup> and palaeoclimatic<sup>15</sup> deductions, this can be considered to be a fairly complete polar wander curve for India for the past 1600 to 1800 m.y. duration.

The Phanerozoic palaeomagnetic data from India and the other Gondwanic continents<sup>6,7,16</sup> are consistent with the Gondwanic reconstructions of du Toit<sup>17</sup> and Smith and Hallam<sup>18</sup>. These reconstructions can therefore be used to study the older palaeomagnetic data from these continents.

Accordingly, the Indian polar wander is recomputed<sup>19</sup> for the India-Africa assembly of the latter reconstruction and compared with the corresponding African curve in Fig. 2. This comparison suggests that India and Africa had not assembled in their early and middle Phanerozoic Gondwanic position until about 75–800 m.y. ago. These data also fail to support Piper's<sup>20</sup> claim that the Precambrian

FIG. 1. Palaeomagnetic polar wander (south pole) track for India. 1: Siwalik redbeds; 2–5: Deccan traps; 6–7: Tirupathi and Satyavedu sandstones; 8–9: Rajmahal and Sylhet traps; 10–13: Pachmarhi, Mangli, Parsora and Himgir sandstones; 14–16: Kamthi beds; 17: Talchir series; 18: Speckled sandstones; 19: Salt Pseudomorph beds; 20: Purple sandstones; 21–22: Rewa and Bhandar sediments; 23: Kondapalle charnokites; 24: Malani rhyolites; 25: Mundwara complex; 26: Lower Sullavals; 27: Kaimur sandstones; 28: Upper Pekkals; 29–30: Bhima sediments; 31: Lower Pekkals; 32–33: Cuddapah sediments; 34–35: Lower Vindhya (B.H.Q. and B.H.J.); 36: Visakhapatnam charnokites-I; 37–38: Horahelli and Chitaldurg dykes; 39: Visakhapatnam charnokites-II; 40: Gwalior lavas; 41: Hyderabad dyke.

India, Africa and Australia came together in the Gondwanic assembly only in the late Proterozoic times. As has been stated earlier, the palaeomagnetic data also suggest that South America and Africa were already joined together at this time<sup>4</sup>.

TABLE I

| Geological interval and age | Rock suites  | Mean pole (south) |           |
|-----------------------------|--|-------------------|-----------|
|                             |  | Latitude          | Longitude |

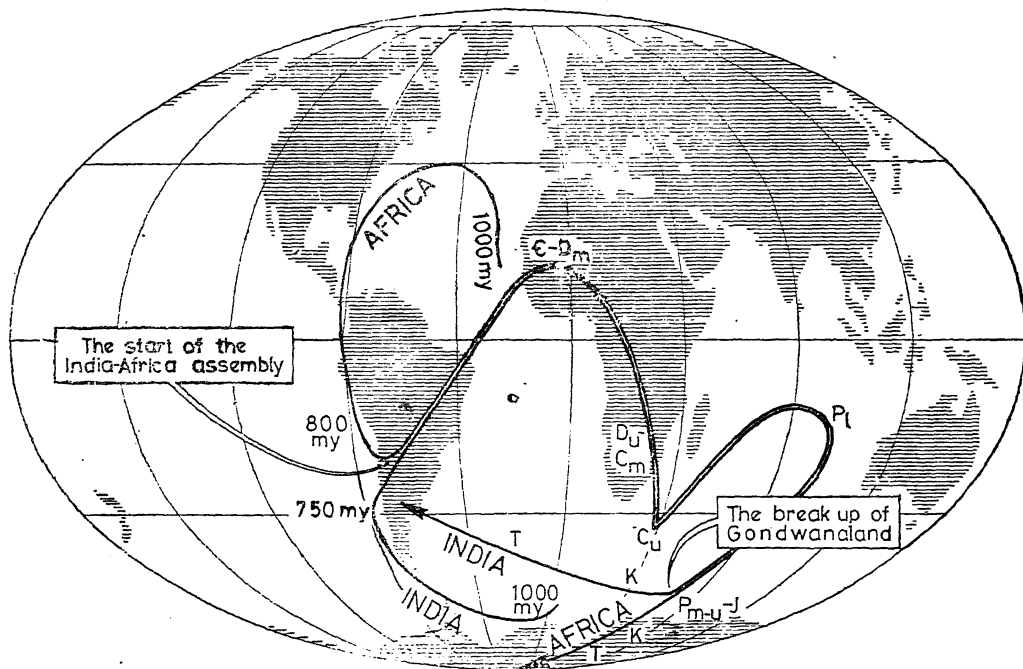

FIG. 2. Comparison of the Indian and African palaeomagnetic polar wander curves. The Indian data, summarised in Fig. 1, recalculated for the India-Africa assembly of the Gondwanic times, i.e., 58.9° clockwise rotation of India, with respect to Africa, with the rotation pole at 28.9° N; 42.2° E. The African polar wander curve is after Brock and Piper<sup>16</sup>.

### 3. AFRO-AMERICAN, GONDWANIC AND EURASIAN SUPERCONTINENTS

The Gondwanic supercontinent obviously resulted from the type of convergent plate motions of which Eurasia<sup>2,22,23</sup> is a latter-day example. The history of Gondwanaland can thus be considered in three stages: (i) the late Proterozoic formative stage of convergent plate motions, (ii) the approximately 700 m.y. long supercontinent stage, and (iii) the late Mesozoic fragmentation stage of divergent plate motions. The inference drawn above suggests that the Afro-American supercontinent<sup>4</sup> fragmented, with the separation of North America about 1000 m.y. ago, long before the Gondwanic supercontinent came into being. This is analogous to the later (late Mesozoic) break-up of the latter which preceded the formation of the Eurasian supercontinent. Another common feature of the three supercontinents (Table II) is their crustal volume (about 2.5 billion Km<sup>3</sup>).

feature in the evolution of the global surface. It will be quite interesting, therefore, to examine whether the supercontinents should be considered to be of intrinsic importance in the framework of the plate tectonics theory. Studying plate interactions in terms of the Feynman graphs for electron-photon scattering in quantum-electrodynamics appears to be a promising attempt<sup>24</sup> in this direction.

The concentrations of the continental crust in the form of supercontinents, as suggested in the foregoing, does not seem to be an exclusively terrestrial phenomenon however. The Martian surface<sup>25</sup>, for instance, is also characterised by a similar feature, i.e., only one supercontinent of rather comparable dimensions.

### 5. ACKNOWLEDGEMENTS

I thank Professor V. L. S. Bhimasankaram for suggesting this study and for many helping discus-

\* Average crustal thickness assumed about 45 Km for Eurasia and about 35 Km for the other two supercontinents.

The continental concentrations on much larger scales also appear to have occurred in the geological past. The palaeomagnetic evidence<sup>3</sup> suggests that Pangaea, with a crustal volume of about 4 billion Km<sup>3</sup>, existed from the Silurian till the Triassic times. This resulted from the merger of Euramerican and Gondwanic land-masses during this period. In case Siberia indeed joined Europe in the Permo-Triassic<sup>3,22,23</sup>, then the Triassic Pangaea must have had the maximum crustal volume (about 4.5 billion Km<sup>3</sup>) amongst the supercontinents that have existed on the global surface during the past billion years. Piper *et al.*<sup>4</sup> have also speculated on the possibility of the concentration of all continental crust in one large mass in the middle Proterozoic times.

### 4. CONCLUSIONS

These observations suggest that the growth and dispersal of the supercontinents have been a major

sions. I have also profited greatly from discussions with Dr. S. M. Naqvi.

## THE ACTION OF CHLORPROMAZINE ON THE SKELETAL MUSCLE OF FROG

S. R. K. ACHARYA AND A. R. GOVINDA RAO\*

Department of Pharmacology, J.J.M. Medical College, Davangere 577004

### ABSTRACT

The action of Chlorpromazine on the skeletal muscle of frog when tested under Gaddum superfusion technique was found to be (1) an anticholinergic effect in small doses and (2) a spasmogenic effect in large doses, this spasmogenic effect was not blocked by curare.

### INTRODUCTION

CHLORPROMAZINE (CPZ) is one of the phenothiazine derivatives widely used in psychiatry and also in the treatment of spastic conditions. The untoward effects of this drug include parkinsonian like symptoms and dyskinetic symptoms which may be mistaken for tetanus, meningitis, poliomyelitis, etc. These symptoms are explained as the effect of the drug on the extrapyramidal system. This work was taken up to find the effect of graded concentration of CPZ on the skeletal muscle.

### MATERIALS AND METHOD

Experiments were carried out on the skeletal muscle of frog *Rana tigrina* under Gaddum superfusion technique<sup>4,5</sup>. The ringer solution prepared according to Burn J. H. (1952) was used. The contractions were recorded on a slow moving smoked drum. Acetylcholine chloride (ACH) was used as an agonist in a dose of 1–2 mcg.

CPZ dissolved in distilled water was used in doses of 0.1, 1, 10, 100 ng<sup>+</sup> and 1, 10 and 100 mcg

in 0.1 ml volume. The effect of CPZ in higher doses like 100 mcg and above were recorded on a stopped drum. In these experiments ACH was not used as an agonist, and they were repeated in potassium-free, calcium-free, sodium-free ringer solution and the solution containing twice the concentration of potassium ion. Tubocurarine 10 mg/ml was used as a blocking agent.

All drugs were dropped from a tuberculine syringe along with ringer solution. The contractions due to ACH were recorded for 20 seconds. After obtaining a set of submaximal contractions due to ACH, the CPZ was dropped followed by ACH after 20 seconds. The inhibition or potentiation of ACH induced contractions by CPZ was expressed as the height of contraction in mm.

### RESULTS

The effects of CPZ on skeletal muscle can be grouped under three headings.

1. Anticholinergic action in doses of 0.1 ng to 10 mcg (Fig. 1).
2. Potentiation of ACH induced contraction in 0.1 ng and 1 ng.
3. A spasmogenic action at 100 mcg and above (Fig. 2).

\* Former Professor and Head of the Department.

TABLE I

Showing the anticholinergic action of CPZ expressed as percentage inhibition of ACH induced contractions in 20 experiments

|                                   | 0.1 ng*         | 1 ng            | 10 ng            | 100 ng         | 1 mcg           | 10 mcg          |
|-----------------------------------|-----------------|-----------------|------------------|----------------|-----------------|-----------------|
| % inhibition $\pm$ standard error | 27.8 $\pm$ 2.34 | 19.5 $\pm$ 0.81 | 24.08 $\pm$ 1.00 | 16.4 $\pm$ 1.2 | 55.9 $\pm$ 1.55 | 48.34 $\pm$ 2.0 |

\*ng = nanogram.

FIG. 1. Showing anticholinergic action of CPZ in doses of 0.1 ng to 10 mcg, each dose of CPZ is followed by 1 mcg of ACH except at 100 mcg.

FIG. 2. Showing the spasmogenic action of CPZ in 100, 200, 300 and 400 mcg, ACH is not used after CPZ.

1. CPZ in doses from 0.1 ng to 10 mcg produced a dose-dependent block of ACH induced contractions on skeletal muscle. The block is directly proportional to the dose at 100 ng to 10 mcg.

2. In 7 out of 20 experiments CPZ in doses of 0.1 ng and 1 ng produced either an immediate or a delayed potentiation of  $17.2 \pm 2.47\%$  of ACH induced contraction of the skeletal muscle. In one out of these 7, the potentiation lasted during the entire course of the experiment, whereas in others it lasted for a short time.

3. *Spasmogenic action*: CPZ when used at 100 mcg and above produced a classic phasic contracture of the skeletal muscle which develops very slowly in over 20-30 minutes. During the first few

minutes the tissue does not exhibit any effect, then slowly, an upward deflection reaching a maximum height of 30-70 mm depending upon the dose. The tissue fails to recover completely even after 6 hours, during which, it remains insensitive to ACH also. This action of CPZ was not blocked even by 200 mcg of curare.

*In ion-free solutions*: In calcium-free solution CPZ failed to produce the spasmogenic effect. In potassium-free solution CPZ produced the contracture of a lesser height and intensity and the tissue recovered on gently pressing down the lever in 40-60 minutes and responded in a graded fashion to the increasing dose of CPZ.

In sodium-free Ringer and Ringer solution containing double the concentration of potassium ion, the tissue developed a contracture.

#### DISCUSSION

The substituted phenothiazines have multiple action on peripheral autonomic nervous system. These include the blockade of nicotinic and muscarinic action of ACH<sup>8</sup>. CPZ is said to produce the relaxation of skeletal muscle in some types of spastic conditions by selectively acting on the gamma efferent system and does not produce a blockade of the neuromuscular junction<sup>2,9</sup>. But a perusal of Table I shows that it blocks the action of ACH on skeletal muscle. The rectus abdominis muscle of frog is one of the preparations used to demonstrate the action of drugs at neuromuscular junction<sup>4</sup>. CPZ produces a curare-like action on the skeletal muscle. In these experiments the anticholinergic action is  $27.77 \pm 2.34$  at first exposure of the tissue to the drug, whereas in next two exposures it is  $19.5 \pm 0.81$  and  $24.08 \pm 0.999$  though the dose of the drug is increased in a graded fashion. This may be because the tissue may show a high initial sensitivity when exposed to the drug for the first time.

The CPZ has also shown a potentiation on the action of ACH on skeletal muscle in dose of 0.1 ng and 1 ng. CPZ is reported to enhance the seizures after its depressant action of a large dose wears off<sup>8</sup>. Also CPZ is said to be an anticholinesterase agent<sup>9</sup>. Therefore the potentiation of ACH action on the skeletal muscle is probably mediated by the anticholinesterase action of the drug.

It may be seen from Fig. 2 that CPZ produces a classic phasic contracture of the skeletal muscle. The fact that it is not blocked by curare, a competitive blocker of the neuromuscular junction and CPZ itself produce a neuromuscular blocking action, shows that the drug produces contracture by acting at a receptor site other than the neuromuscular junction. The next alternative site of action would be the cell membrane or the contractile machinery. The addition of high concentration of potassium to the isolated muscle initiates the classic phase of potassium contracture, but it is not necessarily correlated with the contractility<sup>10</sup>. In potassium-free ringer CPZ produces contracture but relaxes quickly compared to the effect in normal ringer. Its failure to produce this effect in calcium-free ringer suggests that this action is mediated through potassium and calcium ions. CPZ is reported to be having a membrane stabilising action<sup>6</sup>, this demonstrates that the contracture is produced by stabilising the cell membrane, so as to rise the tissue concentration of potassium and calcium ions beyond physiological limits, and more so in a rise of potassium resulting in contracture.

Thus, CPZ is shown to have an anticholinergic action in low doses and a membrane stabilising action resulting in contracture of the skeletal muscle of frog in high dose,

#### ACKNOWLEDGEMENTS

Authors gratefully acknowledge the financial assistance from SBMR, Bangalore. Their sincere thanks are due to Dr. H. Gurupadappa, Principal, for encouragement. The first author is indebted to Dr. Subba Rao for his permission to repeat the work with pure CPZ. The author is grateful to M/s. May and Baker Ltd., Bombay, for their supply of CPZ.

### RADIOCARBON DATES OF SOME LATE QUATERNARY SAMPLES

D. P. AGRAWAL AND SHEELA KUSUMGAR

Physical Research Laboratory, Ahmedabad 380009

PRESENTED below are the <sup>14</sup>C dates of Late Quaternary samples from the coastal and riverine sediments. The eustatic samples are derived from the western coast. Quite a few samples of miliolite formations of Gujarat have also been dated. The river sediments have been <sup>14</sup>C dated for their Stone Age associations.

The samples have been counted in the form of methane in gas proportional counters. The techniques have been described in detail elsewhere (Agrawal and Kusumgar, 1965; Agrawal *et al.*, 1971; Kusumgar *et al.*, 1963). Ninetyfive per cent activity of N.B.S. oxalic acid has been used as a modern standard. For all samples two dates are given in B.P. The first is based on 5568 yr. half-life value and the second, in parenthesis, on 5730 yr. None of the dates has been calibrated for any <sup>14</sup>C/<sup>12</sup>C variations. The dates can be converted to AD/BC scale by using 1950 AD as reference year,

Though CaCO<sub>3</sub> measurements too have been expressed in terms of <sup>14</sup>C dates, yet it has to be noted that CaCO<sub>3</sub> is an inorganic chemical and the <sup>14</sup>C method, strictly speaking, does not apply to it.

These measurements were made at the Tata Institute, Bombay, but now the C<sup>14</sup> lab has been shifted to Physical Research Laboratory, Ahmedabad.

#### ACKNOWLEDGEMENTS

The authors thank Sri. R. V. Krishnamurthy and Sri. R. K. Pant for help in preparing the manuscript.

Asla, Maharashtra India

TF-1178, Late Quaternary, 9750 ± 120  
(10035 ± 125)

Shells from pebbly conglomerate 2.5 m above Krishna river bed at Asla (Lat. 17° 53' N., Long. 73° 59½' E.), District Satara,

**Barda Hill, Gujarat, India**

Mollitic limestone from a running quarry near Barda (Lat.  $21^{\circ} 35' N.$ , Long.  $69^{\circ} 55' E.$ , District Porbandar).

Root of tree extracted at the depth of 14 to 17 m from Kulur (Gurpar) river (Lat.  $12^{\circ} 55' N.$ , Long.  $74^{\circ} 50' E.$ , District Mangalore. Comment: NaOH pretreatment was given. Sample dates a river bed sedimentation.

**Kutch Area, Gujarat, India**

TF-892, Late Quaternary,

$$32530 \pm 2710 \quad (33480 \pm 2790) \\ - 2025 \quad - 2085$$

Miliolite shells collected at a depth of 7.6 m from a limestone bed near Katral hill 13 km from Bhuj Mandvi Road, District Kutch (Field No. 11/92).

TF-893, Late Quaternary,

$$28595 \pm 1600 \quad (29430 \pm 1650) \\ - 1345 \quad - 1380$$

Miliola tests from the surface exposure of the limestone bed at Katral hill, District Kutch. (Field No. 11/26).

TF-897, Late Quaternary,  $12280 \pm 165$   
( $12640 \pm 170$ )

Miliola tests collected from the surface exposure on Bhuj-Naliya road near Drubya hill, District Kutch (Field No. 11/78).

TF-898, Late Quaternary,

$$24760 \pm 1000 \quad (25480 \pm 1025) \\ - 885 \quad - 915$$

Miliola tests from surface exposures on the north flank of Jura hill, District Kutch. (Field No. 11/61).

TF-889, Late Quaternary,  $11130 \pm 150$   
( $11450 \pm 155$ )

Miliolite samples collected at Washtana (Lat.  $23^{\circ} 25' N.$ , Long.  $70^{\circ} 34' E.$ ), District Waga. (Field No. 11/132).

**Nicora, Gujarat, India**

Calcite samples collected from the right bank of river Narmada at Nicora (Lat.  $21^{\circ} 46' N.$ , Long.  $73^{\circ} 7' E.$ ), District Broach.

TF-900, Late Quaternary,  $16825 \pm 225$   
( $17315 \pm 230$ ).

Calcite sample No. 2.

TF-901, Late Quaternary,  $17810 \pm 290$   
( $18330 \pm 300$ ).

Calcite sample No. 3.

**Panambur, Mysore, India**

TF-1089, Late Quaternary,

$$37375 \pm 4960 \quad (38460 \pm 5105) \\ - 3100 \quad - 3190$$

Carbonised wood from ancient coastal sediments at a depth of 11.5 m to 12 m near Punalur Harbour area (Lat.  $12^{\circ} 56' N.$ , Long.  $74^{\circ} 50' E.$ ), District South Kanara.

**Patan, Gujarat, India**

TF-1047, Late Quaternary,  $19645 \pm 315$   
( $20215 \pm 325$ )

Shells from a 50 m thick exposed bed near Patan, District Junagarh. Stratigraphy not clear. (Field No. LOC-7.6/1969).

**Pokran, W. Rajasthan, India**

TF-1214, Late Quaternary,

$$27875 \pm 1985 \quad (28690 \pm 2045) \\ - 1605 \quad - 1650$$

Carbonate sample from concretionary layer about 1 m below aeolian sand, 15 km east of Pokran.

**Rati Karar, M.P., India**

TF-967, Late Quaternary

$$32750 \pm 1770 \quad (33700 \pm 1820) \\ - 1580 \quad - 1625$$

Shells collected at a depth of 11 m from a M.S.A. tool bearing and Late Pleistocene fossiliferous sandy pebbly conglomerate on River Narmada near Rati Karar village, District Narsinghpur.

**Tasgaon, Maharashtra, India**

TF-1213, Late Quaternary,  $3745 \pm 105$   
( $3855 \pm 110$ )

Wood sample 10 m below terrace level on the left bank of River Krishna near Tasgaon (Lat.  $17^{\circ} 2' 30' N.$ , Long.  $74^{\circ} 39' E.$ ), District Sangli. The deposit also yielded late Pleistocene fauna.

**Vembanad Lake, Kerala, India**

Shells extracted from the bed of Vembanad Lake to study the rate of sedimentation.

TF-1090,  $3625 \pm 95$  ( $3735 \pm 100$ )

Shells 3.35 m below the present bed. Sample No. 1.

TF-1091,  $3945 \pm 140$  ( $4060 \pm 145$ )

Shells 1.82 m below the present bed. Sample No. 2.

## LETTERS TO THE EDITOR

## EMISSION SPECTRUM (C-X AND D-X SYSTEMS) OF THE MOLECULE—SrBr

Early investigations on the band spectrum of the diatomic molecule—SrBr had been reported by Oimsted<sup>1</sup> in bunsen flame and Hadfield<sup>2</sup> using Oxy-acetylene flame. Walters and Burrage<sup>3</sup> were the first to observe a group of eleven red degraded bands lying in the violet region. In 1942, Harrington<sup>4</sup> made a more comprehensive study of this molecule employing absorption tubes and classified the observed bands to constitute as many as four distinct systems. He could also identify their sub-heads and vibrational isotopic shifts for many of the bands. Recently, Reddy and Rao<sup>5</sup>, using high frequency discharge source, reported yet another additional system, the E-system, lying in the spectral region  $\lambda\lambda 3000-3200$ .

In the present investigation the band systems lying in the violet and ultraviolet region for this molecule have been recorded in thermal emission, for the first time, using high temperature graphite tube furnace. Practically all of these systems of bands have been fairly extended apart from reporting quite a large number of additional stray bands.

A small quantity of pure solid strontium bromide was placed in the combustion tube of the high temperature vacuum graphite tube furnace. The chamber of the furnace, after evacuation, was filled with argon gas to a pressure of 60 torr, to prevent the rapid effusion of the experimental vapour from the open ends of the tube. The spectrum has been excited at about 2400°C and is recorded on Ilford HP-3 panchromatic plates. An exposure of six to ten minutes was found sufficient using Hilger E-492 large quartz spectrograph.

The  $C^2\Pi - X^2\Sigma$  system known in the spectral region  $\lambda\lambda 3990-4235$  has been extended on both the sides in thermal emission and was recorded to lie in the wavelength region  $\lambda\lambda 3919-4307$ . The bands were found to be double headed and clearly degraded to red. Their  $Q_2$  and  $Q_1$  heads can be well represented by the relation given below.

$$\begin{aligned} \nu_{01, Q_2} &= \frac{24343.68}{2465.81} + \frac{205.56}{204.92} (\nu'' - \frac{1}{2}) \\ &\quad - \frac{0.49}{0.48} (\nu'' - \frac{1}{2})^2 - \frac{216.62}{216.72} (\nu'' - \frac{1}{2}) \\ &\quad - \frac{0.51}{0.52} (\nu'' - \frac{1}{2})^2 \end{aligned}$$

Quite a good number of new bands including new sequences have been identified for this system.

TABLE I

New data and data for the systems C-X and D-X of the molecule—SrBr

| 4181.7                  | 23907                     | 23902 | (14, 17)                         |
| 4186.4                  | 23880                     | 23873 | (18, 21)                         |
| System D-X, P heads     |                           |       |                                  |
| 3317.2                  | 30137                     | 30137 | (11, 7)                          |
| 3529.3                  | 28326                     | 28330 | (0, 3)                           |

Further on the shorter wavelength side a group of single headed bands was photographed in the spectral region  $\lambda\lambda 3317-3529$ . These bands belong to the system  $D^2\Sigma - X^2\Sigma$  and are degraded to shorter wavelength side. The bands for this system were found to be comparatively weak in intensity and

show a wide condon parabola. The wavenumbers of their P-heads can be given by the equation.

$$\nu = 28959 \cdot 17 - 247 \cdot 83 (\nu' - \frac{1}{2})^2 - 0 \cdot 55 (\nu'' - \frac{1}{2})^2 - 216 \cdot 62 (\nu' + \frac{1}{2}) + 0 \cdot 51 (\nu'' + \frac{1}{2})^2$$

A few new bands could also be recorded for this system. Table I represents the wavelengths of the new band heads with their corresponding wavenumbers in vacuum and vibrational analysis, etc., for the C-X and D-X systems.

The E-X system lying in the spectral region  $\lambda\lambda$  3000-3200 also appeared on the photographic plate but only faintly..

## CRYSTAL STRUCTURES OF AMIDOPYRINE AND PHENYLBUTAZONE

As part of a programme of structural studies on analgesics and their interactions<sup>1-4</sup>, we have determined the crystal structures of two well-known analgesics, namely, 1-phenyl-2, 3-dimethyl-4-dimethyl-amino-5-pyrazolone (amidopyrine) and 4-butyl-1, 2-diphenylpyrazolidinedione (phenylbutazone), by x-ray diffraction methods. A preliminary account of these structure analyses is given here.

The space groups and unit cell dimensions of these compounds were reported earlier<sup>1</sup>. However, the cell dimensions of amidopyrine, though essentially correct, were found to be in considerable error and, hence, they were redetermined from oscillation and Weissenberg photographs and refined using high angle Bragg reflections. These cell dimensions and other relevant data along with those reported earlier for phenylbutazone are given below.

**Amidopyrine :** Space group  $P \bar{1}$

$$a = 7 \cdot 458 \pm 0 \cdot 005, \quad b = 10 \cdot 744 \pm 0 \cdot 005, \\ c = 17 \cdot 486 \pm 0 \cdot 015 \text{ \AA};$$

$$\alpha = 98 \cdot 6 \pm 0 \cdot 2, \quad \beta = 88 \cdot 6 \pm 0 \cdot 3, \quad \gamma = 108 \cdot 6 \pm 0 \cdot 2^\circ;$$

$Z = 4$ ;  $D_m = 1 \cdot 176 \pm 0 \cdot 005$ ,  $D_o = 1 \cdot 171 \text{ gm/cc}$ .  
**Phenylbutazone :** Space group  $P2_1/c$

$$a = 21 \cdot 695 \pm 0 \cdot 004, \quad b = 5 \cdot 823 \pm 0 \cdot 002, \\ c = 27 \cdot 881 \pm 0 \cdot 004 \text{ \AA};$$

$$\beta = 108 \cdot 06 \pm 0 \cdot 10^\circ; \quad D_m = 1 \cdot 211 \pm 0 \cdot 020, \\ D_o = 1 \cdot 218 \text{ gm/cc}, \\ Z = 8.$$

Three-dimensional x-ray data from the crystals of amidopyrine were recorded on multiple-film equi-inclination Weissenberg photographs using  $\text{CuK}_\alpha$  radiation for reciprocal levels  $hkl$ ,  $h = 0$  through 6, and  $hkl$ ,  $l = 0$  through 10, and the intensities were estimated visually. The intensity data from the crystals of phenylbutazone were collected on a 4-circle Hilger and Watts diffractometer at the Laboratory of Molecular Biophysics, Oxford. Both the structures were solved by direct methods using the programme MULTAN originally written by M. M. Woolfson, P. Main and G. Germain, and modified for the IBM 360/44 computer in the Institute by S. Ramkumar and M. R. N. Murthy. The solutions were aided by packing considerations and trial calculations. The structures were refined isotropically by the structure factor least squares method. The current R values are 0.16 for amidopyrine and 0.15 for phenylbutazone. The atomic positions at the present stage of refinement are shown in Figs. 1 and 2.

FIG. 1. The crystallographically independent molecules in the structure of amidopyrine as viewed along the  $a$ -axis.

Both the structures contain 12 molecules in the asymmetric part. In each structure, the crystallographically non-equivalent molecules have comparable bond lengths and angles. The dimensions of the pyrazolone ring in the amidopyrine molecule are broadly similar to those observed in the structure of antipyrine. The hetero nitrogen atoms in the ring are pyramidal. In the structure of phenylbutazone, the two C=O bonds in each molecule have lengths appropriate to a C=O double bond and, hence, neither of the oxygen atoms is protonated. The tetrahedral character of the carbon atom at the 4-position indicates that a hydrogen atom is attached to it. The two nitrogen atoms in the five-membered ring are pyramidal and the attached phenyl rings are *trans* about the N-N bond.

FIG. 2. The crystallographically independent molecules in the structure of phenylbutazone as viewed along the *b*-axis.

Further refinement of the structures is in progress. Details of the analyses and the final results will be published elsewhere.

The authors thank Professor G. N. Ramachandran and Professor V. S. Venkatasubramanian for their interest in this work and Professor Dorothy

Waller for making her diffractometer available to us for data collection from the crystals of phenylbutazone.

## EMISSION SPECTRUM OF PHENYLACETYLENE

THE emission spectrum of phenylacetylene has been studied although its ultraviolet absorption is reported by Padhye *et al.*<sup>1</sup> since we believe that generally the emission spectrum of a molecule yields more information on the ground electronic state than its absorption spectrum. The results obtained by us on the ultraviolet emission spectrum of phenylacetylene vapour are reported here.

The emission spectrum of phenylacetylene was excited by an uncondensed transformer discharge at about 1,500 volts through the flowing vapour of the substance in a  $\pi$ -type discharge tube of diameter 1.6 cm and length, 40 cm. The spectrum was photographed on a medium quartz spectrograph with an exposure of about 5 hours. The spectrum occurring in the region  $\lambda = 2715 \text{ \AA} - 3095 \text{ \AA}$  consisted of about 40 bands overlapped by a fairly strong continuum.

With the band at  $36369 \text{ cm}^{-1}$  chosen as the 0, 0 band which agrees well with the position ( $36,370 \text{ cm}^{-1}$ ) obtained in the absorption spectrum<sup>1</sup>, all the bands in the spectrum could be analysed in terms of 2 upper state and 13 ground state fundamental frequencies. Table I gives the band data and their assignments and also the nature of vibrations of the fundamental frequencies. Also in the parentheses are given in the same table, the Raman and infrared data<sup>2</sup> for comparison. In addition, frequencies, 60 and  $101 \text{ cm}^{-1}$ , have been observed as combination bands. These are probably due to  $v-v$  transition of some non-totally symmetric vibrations.

The symmetry of the molecule is represented approximately by the point group  $C_{2v}$  and the

### TITRIMETRIC DETERMINATION OF MILLIGRAM AMOUNTS OF COPPER

A GRAVIMETRIC procedure for the determination of copper as cuprous thiocyanate using ammonium thiocyanate both as reagent and precipitant was developed<sup>1</sup>. We have now evolved a titrimetric procedure by combining the gravimetric method mentioned and the Volhard's procedure<sup>2</sup> for the determination of copper. This new procedure permits determination of milligram amounts of copper.

**Procedure.**—A known volume of the standard copper sulphate solution was mixed with about 45 ml of glacial acetic acid and the contents were diluted to ca. 150 ml. The solution was then heated on a boiling water bath for about 30 minutes and a freshly prepared 10% ammonium thiocyanate solution was added drop by drop with constant stirring till the precipitate was just observed. About 5 ml of water were added and the heating continued till the supernatant liquid was clear. The contents of the beaker were kept at room temperature for 2 to 3 hours and the precipitate was filtered through a No. 4 sintered glass crucible. The precipitate was washed four to five times with cold 0.1% ammonium thiocyanate solution and finally with 20% ethanol till the precipitate was free from soluble thiocyanate. The precipitate was then dissolved in a requisite quantity (20–25 ml) of liquor ammonia. The solution collected in the buchner flask was quantitatively transferred into a 250-ml conical flask and mixed with nitric acid (6 N) until the cuprammonium blue disappeared followed by two to three ml in excess. A known excess of standard silver nitrate solution (0.05 N) was added. Ferric alum indicator (1 ml) was then added and the excess silver nitrate back-titrated with standard ammonium thiocyanate (0.05 N) solution.

TABLE I

*Volumetric determination of copper via precipitation with ammonium thiocyanate*

| Sl. No. | Copper, mg |        | Error % |
|---------|------------|--------|---------|
|         | Taken      | Found  |         |
| 1       | 5.610      | 5.595  | − 0.27  |
| 2       | 11.220     | 11.290 | − 0.62  |
| 3       | 16.830     | 16.920 | + 0.54  |
| 4       | 22.440     | 22.570 | + 0.58  |
| 5       | 28.050     | 28.130 | + 0.29  |

The results recorded in Table I clearly show that milligram amounts of copper could satisfactorily be determined by this method. Moreover, this titrimetric procedure could be extended for the determination of copper in ores and alloys, since copper could be precipitated as cuprous thiocyanate in presence of several other metals.

### SPECTROPHOTOMETRIC STUDY OF SCANDIUM CHELATE WITH 2, 2'-(ETHANE-DIYLIDENEDINITRILE); DIPHENOL (GBHA)

The Schiff base GBHA is prepared by the reaction of glyoxal and O-aminophenol<sup>1</sup>. The GBHA is colourless but its chelates with metal ions are intense violet to red. The analytical applications of GBHA have been surveyed by Jungreis and Thaber<sup>2</sup>. Vrchlabsky and Bocek<sup>3</sup> have used GBHA for the determination of Sc (III) in aqueous solution. In the present work scandium (III) complex with GBHA has been studied by extraction in *n*-butanol in presence of acetate and perchlorate ion. In this procedure wavelength for maximum absorbance remains same but there is an eight-fold increase in intensity.

A Unicam spectrophotometer, SP 600 and a Metrohm pH-meter, E-350 were used for measuring the absorbance and pH's of the solutions. Solution of the ligand of appropriate strength was prepared in *n*-butanol. Scandium (III) solution was prepared by dissolving Sc<sub>2</sub>O<sub>3</sub> (G.R. Merck) in perchloric acid and solution made up to the mark with double distilled water. All other chemicals used were of reagent grade.

**Recommended procedure.**—To suitable aliquots of Sc (III) add excess GBHA in *n*-butanol in presence of acetate and perchlorate ions at pH 5–10. The solutions are then shaken for about two hours. The two layers are separated and absorbance of the complex is then measured against the corresponding reagent blank.

**Absorption spectra of the complex.**—Solutions containing Sc (III) and GBHA in ratio 1 : 50 were taken in the pH range 4.0 to 7.0. The complex extracted with *n*-butanol and spectra were recorded against the reagent blanks. The complex found to exhibit maximum absorbance at 560 nm in the pH,

range 4.80 to 5.30. Beyond this pH, the absorbance falls sharply.

**Stability of the complex.**—The reddish violet colour of the complex is extracted completely in *n*-butanol in two hours and colour intensity was found to be stable for 42 hours at  $25 \pm 1^\circ$ .

**Characteristics of the complex.**—The molar composition of the complex as deduced by Asmus<sup>4</sup> and Bent and French<sup>5</sup> was found to be 1:1. The system obeys Beer's law up to 3.8 ppm of scandium (III) at pH 5.0 and at  $\lambda = 560$  nm. The sensitivity of the colour reaction is  $0.0044 \mu\text{g Sc/cm}^2$  for  $\log I_0/I = 0.001$ . The optimum range for accurate determination as obtained from Ringbom plot<sup>6</sup> is 1.2 to 3.0 ppm.

**Discussion.**—Vrchlabsky and Bocek<sup>3</sup> have studied Sc (III)—GBHA system and reported that when scandium (III) solution is heated with an aqueous ethanolic solution of GBHA in presence of  $\text{NH}_4\text{NO}_3$  at pH 2.5 to 5.0, it forms a reddish complex which has an absorption maximum at 560 nm and sensitivity is  $0.033 \mu\text{g/cm}^2$ . They have also reported that acetate masks the reaction.

In the present work the species formed is extracted in *n*-butanol readily. No heating is required and the acetate ions do not interfere. The sensitivity is about 8 times more as compared to the sensitivity in aqueous medium. The 1:1 complex of scandium and GBHA is stable up to 42 hours whereas the species in aqueous solution is stable for a much shorter period.

# SPECTROPHOTOMETRIC DETERMINATION OF OSMIUM WITH $\beta$ -BENZOYL- $\alpha$ -(*o*-TOLYL) THIOUREA

THE organic reagent, thiourea and its derivatives have been used for the spectrophotometric determination of osmium<sup>1-3</sup>. The present author has introduced benzoylthioureas, as sensitive and highly selective reagents for the same element<sup>4,5</sup>. In this communication, is described the use of one such reagent,  $\beta$ -benzoyl- $\alpha$ -(*o*-tolyl) thiourea, for the

spectrophotometric determination of osmium. The orange-yellow complex of osmium formed with the reagent is soluble in ethanol and in a number of other organic solvents. In solvents like ethanol and chloroform the complex obeys Beer's law over a useful range of concentration of osmium and microgram amounts of the element can be determined in presence of a large number of foreign ions. Besides the analytical aspects, studies have also been made with regard to the composition and dissociation constant of the complex in solution utilising spectrophotometric methods.

The reagent was prepared by the method reported earlier<sup>1</sup>. A 0.5% solution of the reagent in ethanol was used. A standard osmium (VIII) solution was prepared as reported in an earlier communication<sup>6</sup>. A Unicam SP 600 spectrophotometer was used for absorbance measurements. All other solutions were prepared from reagent grade chemicals.

**Procedure.**—A standard aliquot of osmium (VIII) solution was treated with 3 ml of 0.5% ethanolic solution of the reagent. The acidity of the solution was adjusted to 6 N with conc. hydrochloric acid. After the addition of 5 ml of ethanol, the solution was heated for ten minutes over a boiling water bath. The mixture was cooled and made up to 25 ml with ethanol. The solution can also be extracted with chloroform and the extract diluted to 25 ml with the same solvent. The absorbances of the solution thus obtained was measured against a blank prepared similarly.

**Results and Discussion.**—The osmium complex was found to be soluble in ethanol, chloroform, carbon tetrachloride, ethyl acetate, amyl acetate, amyl alcohol and tri-*n*-butylphosphate. In ethanol and chloroform the complex shows maximum absorption at 400 nm and all the measurements were carried out at this wavelength. In both these solvents Beer's law is obeyed from 3 to 21 ppm of osmium and the Ringbom plot<sup>7</sup> shows the optimum range of 6 to 18 ppm. The maximum colour intensity is observed in 4–8 N HCl and 2 ml (or more) of the reagent solution was necessary for full development of colour. The Sandell sensitivity<sup>8</sup> of the colour system was found to be  $0.028 \mu\text{g/cm}^2$  and the per cent. relative error<sup>9</sup> was 2.72%. The molar absorptivity was 6800.

The composition of the complex in solution was ascertained by the Job's method<sup>10</sup> and the molar ratio method<sup>11</sup>. Both the methods indicated the formation of a 1:1 complex.

The dissociation constant was evaluated from the Job's method of nonequimolar solutions<sup>12</sup> and the method of Harvey and Manning<sup>13</sup>. The dissociation constant, *K*, was  $8.1 \times 10^{-4}$  by the Job's

method. K<sub>2</sub> as calculated from the Harvey and Manning equation was 3.0 × 10<sup>-4</sup>.

With the help of this equation the value as 6 ppm of osmium VIII can be determined after extraction of the complex into chloroform in presence of 4.0 ppm of the ions of Al<sup>3+</sup>, Ti<sup>4+</sup>, Fe<sup>3+</sup>, Mn<sup>2+</sup>, Ba<sup>2+</sup>, Na<sup>+</sup>, UO<sub>2</sub><sup>2+</sup>, As<sup>3+</sup>, Hg<sup>2+</sup>, ZrO<sub>2</sub><sup>2+</sup>, V<sup>5+</sup>, Mg<sup>2+</sup>, Cd<sup>2+</sup>, Cu<sup>2+</sup>, W<sup>6+</sup>, Ca<sup>2+</sup>, Ba<sup>2+</sup>, Sr<sup>2+</sup>, Bi<sup>3+</sup>, Co<sup>2+</sup>, Cr<sup>3+</sup>, Zn<sup>2+</sup>, La<sup>3+</sup>, Th<sup>4+</sup>, Sb<sup>3+</sup>, Pb<sup>2+</sup>, chromate, manganate, oxalate, phosphate and the rare earths, and 100 ppm of In<sup>3+</sup> and Pd<sup>2+</sup> and 40 ppm of Rh<sup>3+</sup> and Pt<sup>4+</sup>. Interference due to palladium was avoided by prior removal as its azide complex. However, the ions of Cu<sup>2+</sup>, Ag<sup>+</sup>, Au<sup>3+</sup> and Ru<sup>3+</sup> interfere with the determination.

The author wishes to express his deep sense of gratitude and indebtedness to Prof. Dr. A. K. Majumdar, Senior Professor of Chemistry, Jadavpur University, Calcutta-32, for his keen interest and valuable suggestions.

# FLEMISTRICTIN-A, A NEW CHALCONE FROM THE LEAVES OF *FLEMINGIA STRICTA* ROXB. (LEGUMINOSAE)

IN continuation of our work on the chemical examination of the plants belonging to the genus *Flemingia* (Leguminosae), we have examined the leaves of *F. stricta* Roxb. from the hexane extract of which a new prenylated chalcone designated as flemistricitin-A has been isolated.

The hexane extract of the dried powdered leaves on concentration gave a greenish yellow residue

which was subjected to column chromatography on silica gel (20 g) with benzene : hexane (3 : 1) and eluted successively with benzene : hexane (3 : 1), benzene and benzene (fraction-2). The later fractions of benzene : hexane (3 : 1) eluate on concentration gave waxy material. Most of the leaves were removed by crystallisation from methanol and the residue from the filtrate on crystallisation from hexane gave orange-yellow needles of flemistricitin-A.

Flemistricitin-A melted at 164° (Found C 77.91, H 6.28, C<sub>20</sub>H<sub>20</sub>O<sub>2</sub> requires C 78.02, H 6.49%). M<sup>+</sup> 308. It gave characteristic test for chalcones with SnCl<sub>4</sub> in CCl<sub>4</sub>.  $\lambda_{\text{max}}^{\text{EtOH}}$  215 and 356 nm.  $\mu_{\text{max}}^{\text{NaCl}}$  3150 (hydroxyl), 1620 (chelated carbonyl) and 1370 cm<sup>-1</sup> (gem-dimethyl group). The 60 MHz NMR spectrum of flemistricitin-A in CHCl<sub>3</sub> showed an AB quartet (7.93, 7.50 J<sub>trans</sub> = 16 Hz) and a chelated hydroxyl at 14.33 (singlet, disappeared on D<sub>2</sub>O exchange) providing evidence for the chalcone system. A doublet at 3.50 (2H, J = 7 Hz) for an Ar-CH<sub>2</sub>-, a vinylic hydrogen adjacent to a CH<sub>2</sub> at 5.30 (1H, triplet) and two singlets at 1.80 (3H) and 1.87 (3H) for two methyl groups on olefinic carbon atom showed the presence of a 3,3-dimethylallyl group attached to an aromatic ring. The two ortho-coupled protons on ring B appeared at 6.45 (1H, doublet, J = 9 Hz) and 7.30 (1H, doublet, J = 9 Hz) and the five aromatic protons on ring A appeared as a multiplet between 7.10–7.40. Mass spectrum of flemistricitin-A showed a molecular ion m/e 308 and other fragment ions at m/e 293 (M-15), m/e 275 (M-18-15), m/e 265 (M-43), i.e., (M-C<sub>3</sub>H<sub>7</sub>), m/e 252 (M-56), i.e., (M-C<sub>4</sub>H<sub>8</sub>), m/e 231 (M-77), m/e 204 (M-104), m/e 175 (M-77-56) and m/e 148 (M-104-56).

The peaks at 104 and 77 clearly indicated the unsubstituted nature of ring A. From the above data flemistricitin-A has been assigned structure I.

The structure of hemistriclin-A has been confirmed by its synthesis.  $\beta$ -Resacetophenone was prenylated<sup>1</sup> using methanolic KOH and the 3-C-prenyl derivative was subjected to chalcone condensation with benzaldehyde. The product was purified by column chromatography over silica gel using benzene as eluant. The compound crystallised as orange-yellow needles which was identical with the natural compound in all respects (m.p., m.m.p., UV, IR, and NMR).

The benzene eluate (fraction-2) on concentration and crystallisation from methanol gave colourless crystals, m.p. 138°; identified as  $\beta$ -sitosterol by direct comparison with an authentic sample (m.m.p. and co-TLC).

We are thankful to Dr. M. Ananthaswamy Rao, Deputy Director, Botanical Survey of India, Dehra Dun, and Dr. P. S. Prakasa Rao, Department of Botany, A.U.P.G. Centre, Guntur, for the supply of plant material and identification. One of us (J. M. R.) thanks C.S.I.R. for the award of Research Fellowship.

# SYNTHESIS OF N-(1-MERCAPTOPHENYL)- N'-PHENYLTHIOUREA AS A CHELATING AGENT

THE preparation of N-hydroxy-N'-diaryl thioureas and N-(1-hydroxyphenyl)-N'-phenyl thiourea and their use as chelating agents have been reported in the literature<sup>1</sup>. The latter compound was obtained by condensing o-aminophenol with phenylisothiocyanate in refluxing dry ether. We found that under identical experimental conditions, condensation of o-aminobenzenethiol with phenyl-isothiocyanate was difficult. The yield of the condensation product was very poor, the dimerized compound (C) being the major product. However when mild reducing conditions were employed, the yield of the desired product (D) could be increased considerably.

When a pinch of zinc dust and about 0.1 ml. of concentrated sulphuric acid were added to the ether solution of (A) and (B) and the solution refluxed for three hours, (D) was the major product of the reaction. The yield of (D) could still be increased, first by dimerizing (A) to yield (C), and then condensing (C) with (B) and finally reducing the condensed product with Zn dust and sulphuric acid.

The compound (D) is readily susceptible to air-oxidation, hence it was stored in sealed tubes, and all the reactions carried out in an inert atmosphere of nitrogen. The n.m.r. spectrum of (D) taken in CDCl<sub>3</sub> shows a broad signal around 4.5  $\delta$  accounting for three protons (2NH, one SH). The aromatic region between 6.5-7.2  $\delta$  corresponds to 5 shielded aromatic protons which may be due to hydrogens at 2', 6', 3, 6, and 4 (or 5), while a strong signal appears around 7.3-7.5  $\delta$  which can be assigned to those at 3', 4', 5' and 5 (or 4).

The compound (D) readily forms complexes with bivalent transition metals like Cu<sup>+2</sup>, Ni<sup>+2</sup>, Co<sup>+2</sup>, etc. The elemental analysis given in Table I

TABLE I  
Elemental analysis

| Compound   | Elemental Analysis |       |       |       |       |       |         |       |
|------------|--------------------|-------|-------|-------|-------|-------|---------|-------|
|            | % C                |       | % N   |       | % S   |       | % Metal |       |
|            | Cal.               | Found | Cal.  | Found | Cal.  | Found | Cal.    | Found |
| Ligand     | 60                 | 59.85 | 10.76 | 10.6  | 24.61 | 24.7  |         |       |
| Cu-complex | 53.65              | 53.5  | 9.62  | 9.42  | 23.7  | 23.5  | 10.91   | 10.81 |
| Ni-complex | 54.11              | 54.00 | 9.71  | 9.62  | 23.93 | 23.8  | 10.18   | 9.95  |
| Co-complex | 54.1               | 54.1  | 9.69  | 9.62  | 23.9  | 23.83 | 10.17   | 9.87  |

clearly indicates that the Metal : Ligand ratio in the complexes is 1:2 and their infrared spectra data strongly suggest that their structures are analogous to the complexes of the same metals with  $N$ -(1-hydroxyphenyl)- $N'$ -phenyl thiourea<sup>1</sup>.

**A. Synthesis of the Ligand—*p*-aminobenzensulpho-**  
13 g. and phenyl isothiocyanate (14 g.) were added to a mixture of 25 ml. of dry ether and 0.5 ml. of concentrated  $H_2SO_4$ . Zn dust was then added to this mixture and refluxed under nitrogen for three hours. On cooling, a solid separated out. After removing the ether, the solid was extracted with 2N sodium hydroxide. The solution was filtered and the compound was regenerated from the filtrate by dropwise addition of glacial acetic acid with constant stirring. The solid was filtered and recrystallised from ethanol.

**B. Synthesis of complexes.**—Equimolar alcoholic solutions of the ligand and metal-nitrates ( $Cu^{++}$ ,  $Ni^{++}$ ,  $Co^{++}$ ) were mixed separately and kept in deep freeze overnight. The precipitates obtained were removed by filtration and washed with alcohol to remove the excess of metal-nitrates. The resulting complexes were recrystallised from alcohol.

## EVIDENCE OF RELICT SALINITY AND MARINE TRANSGRESSION IN THE SHALLOW SOUTH- WESTERN FRINGE OF THE NARMADA UPLAND ALLUVIAL VALLEY OF MADHYA PRADESH

OCCURRENCE of the deteriorating quality of water from the Timurni Block of Seoni Malwa Region of Madhya Pradesh was first recorded by A. S. M. Rao (1961) from the well at Pokharni (22° 25' 77" 13'). To delineate the pockets of salinity, seven samples from the fringe belt were subjected to chemical analysis. Electrical conductivity of these samples varies from 960 to 6,750  $\mu$ mhos/cm at 25°C, suggesting a sudden deterioration in quality towards the fringe belt of the region. There are indeed six such isolated pockets in the area, namely, Rala, Tajpura-Pokharni-Timurni, Gurari, Dhanpura, Sirkhamba and Bariaon. The high values of electrical conductivity are further supported by the sympathetic values of the chloride ions, and the abnormally high value of 1,470 ppm of chlorides at Naosar. Further, it has been observed in the case of Pagdhal (22° 25' 77" 21') borehole, in the same area, that the salinity increases

with depth. In the diamond-shaped Piper diagram all the water samples fall essentially in areas 6 and 7, indicating noncarbonate hardness and noncarbonate alkali (Primary Salinity) respectively. All the water samples are thus in conformity with the mines and ocean waters. In the Collins bar diagram, the ratio of  $Cl$  to  $CO_3 + HCO_3$  varies from 1.5 to 26, suggesting again a rapidly deteriorating quality of water. Indeed water sample from Bariaon in the south-western trappean fringe belt has reached a very high ratio of 26 to confirm the relict salinity of the highest order matching with the sea-shore salinity, and thereby confirming also the evidence of marine transgression in the area and the link of the erstwhile channel of the Narmada with that of the Tapi-Purna.

Hence the marine transgression of the Eocene times has not only connected the Arabian Sea with the Purna valley through the arm of the Tapi valley (Adyalkar, 1963, p. 37) but also provides an access to the Narmada valley, and that the river Tapi served as the sole channel outlet for the entire Tapi-Purna-Narmada river system of post-Eocene times. Similar study of quality deterioration leading to the marine transgression was earlier demonstrated by Adyalkar *et al.* (1969) to explain the marine transgression of Middle Jurassic epoch along the Lathi-Jaisalmer contact in Jaisalmer District of Rajasthan.

This also brings home the fact that the Taylor's Sixth Groundwater Province (Taylor, 1959, p. 695) comprising Cainozoic Fault Basins of Peninsular India was a more composite unit with two major rivers of Narmada and Tapi having a remarkable westerly drainage. It was indeed a unique lake region of the Eocene times with a single channel of the Tapi serving as an outlet for both the tributaries, the Purna and the Narmada, flowing over the silted lake basins until the Pleistocene times, when the present topography came into existence with change in the course of the river Narmada to its present channel.

# PHOSPHATIC ALGAL STROMATOLITES IN THE TRANS ARAVALLI VINDHYANS OF BADI KHATU, DISTRICT NAGOUR, RAJASTHAN

A NEW horizon of Algal Stromatolites has been discovered in the Trans Aravalli Vindhyan limestone around Badi Khatau (27° 7' : 74° 19'). District Nagaur, Rajasthan. The limestone with the algal structures occupies the top position in the sequence of Vindhyan rocks, i.e., on the top of the flat topped hills of Vindhyan rocks, resting unconformably over the Aravalli meta sediments in the plains of recent alluvium. Here the Vindhyan rocks have a gentle dip (about 10°) towards North-West with the North-East South-West strike, whereas the Aravalli rocks are folded and refolded. The lithology and the texture of the Vindhyan rocks here indicate the marine littoral environment of deposition, not very far off from the source where the continuous wave action resulted in good sorting of the underlying sandstone with angular grains. The underlying sandstone also shows sedimentary structures like bedding, cross-bedding, graded-bedding, ripple marks and other shallow water surface-structures. The geology of the region is well established through the work of Heron (1953), Krishnan and Swaminath (1959), Roy Choudhary *et al.* (1965) and Misra (1969).

Here, the uppermost rock unit of Vindhyan, on which the algal structures have grown in ferruginous and conglomeratic calcareous rock with slight angular fragments of quartz, agate, chert and limestone bounded by the ferruginous lime mud.

## GEOLOGICAL MAP OF KHATU AREA (BY A. P. HERON)

One very important aspect about the stromatolites of this area is that they have grown upto only a few inches in height. This phenomenon might have taken place due to the check in the growth of the algal stromatolites caused by the upheaval of the basement or change in the climatic conditions favourable for their growth. No doubt the later weathering has also played an important role in reducing the original thickness of the stromatolitic horizon.

The algal stromatolitic assemblage observed in this area includes : Weedia, Conophyton, Collenia-Columbaria, Fenton and Fenton, Collonia Baicalica-Maslov, Collonia Kuisensis-Maslov, Collonia Symmetrica, Krylov and Minjaria Calceolata-Korolyuk Minjaria Uralica. The characters of the individual species are similar to those described by Valdiya (1963) and Benerjee (1971). Mostly the stromatolite species are phosphatic in nature.

In a number of forms the black shining colophane is commonly coated on both sides of the individual laminae and sometimes it completely surrounds the algal structure. Mineral dehlite is also quite common. At the base of the algal structures the fragments of quartz, agate, chert and limestone are generally present. In some forms lime mud together with rock fragments has also occupied the intercolumnar spaces of the algal structures. Iron in form of hematite and limonite has completely altered the horizon containing the algal structures. The area openly invites the extensive studies.

Author expresses his gratitude to Mrs. S. Paliwal for her enthusiastic assistance. Help received from colleagues Mr. Khandelwal, Mr. Khan and Mr. Chauhan is also gratefully acknowledged.

## ON THE SQUAT LOBSTER, *THENUS ORIENTALIS* (LUND) OFF VISAKHAPATNAM (BAY OF BENGAL)

*Panulirus polyphagus* (Herbst), *Panulirus ornatus* var, *Panulirus dasyptus* (H. Milne Edwards) and the deep sea *Puerulus sewelli* are common species of spiny lobsters and *Thenus orientalis* (Lund) and *Scyllarus sordidus* are common among the squat lobsters<sup>1</sup>.

*Tetralia orientalis* is common in the catches and is available more or less throughout the year with the peak during December to March, the breeding season of the animal. *Tetralia orientalis* and the related form, namely *Scyllarus solidus* are comparatively rare in the catches along the Bombay coast (Chhapgar and Deshmukh).

Berried females are available from December to July with a peak during winter season.

Some characters of *T. orientalis* from Visakhapatnam: body depressed; carapace broader than long; stalked eyes at the outer angles of the carapace; carapace and abdomen with granules or tubercles; abdominal segments with median ridge. 5th abdominal segment with three spines on each side and median comparatively bigger spine. Colour of the animal muddy grey. Dimensions of the animal are as follows:

| Sex         | Total length in mm | Carapace length in mm | Carapace breadth in mm | Total weight in gm |
|-------------|--------------------|-----------------------|------------------------|--------------------|
| ♀ (berried) | 248                | 85                    | 99                     | 269.8              |
| ♂           | 234                | 79                    | 94                     | 254.0              |

The estimated total number of eggs of the berried female is 12,467 with an average diameter of 1.1204 mm. Berried specimens are also found with mature and maturing ova, indicating that the species might spawn more than once in the same year.

*T. orientalis* had been recorded from India by White (1847), Neuman (1865), Orman (1891), Thompson (1901), from Madras by Heller (1865) and Henderson (1893), from Mundapam by Prasad and Tampi (1957), from Orissa coast by Alcock (1902) and from Bombay coast by Chhapgar and Deshmukh (1964). Prasad and Tampi<sup>2</sup> and Chhapgar and Deshmukh<sup>1</sup> have suggested that the winter is the breeding period, although Prasad and Tampi<sup>2</sup> mentioned a case of berried female caught in July and the larvae hatched in the same month. The world distribution ranges from Mauritius, Red Sea, Persian Gulf, East Indies and Australia to China.

I am grateful to Prof. K. Hanumantha Rao for his guidance. Thanks are also due to the Government of India for providing the financial assistance under the Bangladesh Scholarship grant.

## ON A RARE BRACHYURAN CRAB ZOEA FROM THE SOUTH-WEST COAST OF INDIA

While sorting out the brachyuran larvae from the plankton samples collected by the U.N.D.P. Pelagic Fisheries Project from the south-west coast of India, an interesting brachyuran zoea with four lateral carapace spines was obtained from a sample from a station off Kasargod covered by the vessel 'Sardineilla' on 6-1-1972. Records of zoea having four lateral carapace spines are very few and such a larva has not so far been reported from the Indian waters.

Length of the zoea from the tip of the rostrum to the tip of the dorsal spine is 6.3 mm. The larva is characterised by the presence of a dorsal, rostral and four lateral carapace spines with small sharp spinules on its surface. All the four lateral spines (Fig. 1) show small enlargements at their extremities. In the abdomen, the 6th segment is separated

FIG. 1. 3rd zoea of *Tetralia* sp.

from the telson. The second abdominal segment has lateral spinular process on either side midlaterally. segment 3 is without any spine, while the 4th and 5th segments have each a prominent spine postero-laterally. Forked telson with long and slender arms bears 3 + 3 inner plumose spines. Of the two lateral spines on the sides one is dorsal in position. Posterior to the 3 inner spines, a small spine is seen only on one side. A small stump seen under high magnification in its place on the other side suggests that it might have been broken and lost. The presence of rudimentary buds of the

pleopods and the development of other appendages indicate that it is in the early 3rd zoeal stage.

The specimen with pairs of lateral spines on the carapace resembles the zoea of the xanthid crab *Tetralia glaberrima* (Herbst) described by Gurney<sup>1</sup> and Al-Kholy<sup>2</sup>, from the Red Sea. But an important difference noticed in the present specimen from their descriptions and figures is that the lateral spines are expanded at the tips. Such a zoea with two pairs of lateral spines having expanded tips has been figured by Dohrn<sup>3</sup>. Williamson<sup>4</sup> has also figured an unknown larva (Fig. 521) from the Atlantic with the same character of expanded extremities of lateral spines. But neither the lateral processes on the abdominal somite 2 nor the lateral spines on the telson found in the present specimen, as well as in the larva of *Tetralia glaberrima*, are seen in the figure by Williamson<sup>4</sup>. However, it could be said with certainty that the present zoea belongs to the genus *Tetralia*.

Most of the characters of the zoea agree well with those of the 3rd zoea stage of *Tetralia glaberrima*. But the important differences noticed are the expansion of the tips of the lateral carapace spines and the larger size of the larva. Along with these the absence of any spine on the 3rd abdominal somite makes it difficult to say that this is the larva of *Tetralia glaberrima* which is the only species of the genus recorded from the Indian waters<sup>5</sup>. Perhaps the larva belongs to some other species of *Tetralia* as yet not recorded from these waters.

## STUDIES ON *GRAPHIOLA PHOENICIS* (MOUG.) POIT.

### I. Histopathological Effects

*Graphiola phoenicis* (Moug.) Poit., the common false smut, occurs in the form of cup-shaped fruiting bodies on both the surfaces of pinnae, all round the rachis and on the leaf bases of *Phoenix sylvestris* Roxb. It is widely distributed in India,

Algeria, Egypt, Italy, Austria, Germany, Holland, Belgium, England and United States (Smith<sup>1</sup>). Except the work of Fischer<sup>2</sup> and Sharma<sup>3</sup> on the morphology, and Millard<sup>4</sup> on the cytology of this systemically controversial fungus, much work has not been done on other aspects, and practically the genus has been completely overlooked for its histopathological effects on the host.

The pathogen occurs on the leaves of *Phoenix sylvestris* in the form of black spots having the cup-like structures called "fruiting bodies". The latter consists of black, circular peridium surrounding the internal light yellow coloured sporogenous filaments and fascicles of sterile hyphae protruding out from the cup.

The mycelium is well developed, intercellular or sometimes intracellular, septate and branched. It forms a compact felt-like mass below the epidermis, from where arise sterile as well as fertile hyphae.

Considerable effect is produced on the various tissues of the lamina of infected host. The infection starts from the periphery and gradually spreads towards the centre of lamina.

Epidermal cells in the normal uninfected lamina are oblong or globose in shape, measuring  $3.99 \mu$  in length and  $2.66 \mu$  in breadth. After the development of the fruiting bodies, the epidermis is destroyed and sloughs off. The mycelium accumulates below the epidermis that gradually causes to raise the epidermal cells. They are later on distorted and ruptured in fragments at places to create spaces for developing mycelium that forms the fruiting body. Below the fruiting body, even remnants of epidermal cells are not present. Epidermal cells, adjoining the fruiting bodies become oval or rounded, are hypertrophied, and measure upto  $9.31 \mu$  in length and  $6.65 \mu$  in breadth. In some cells, the protoplasm shrinks and migrates towards the periphery (Fig. 1).

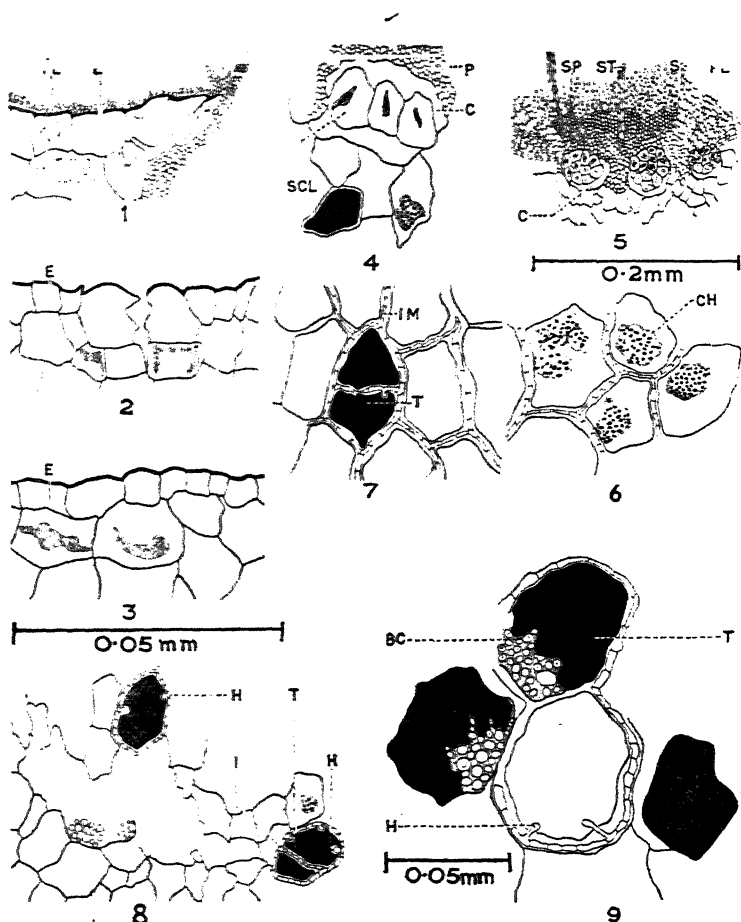

Hypodermal cells in the uninfected regions are cubical or slightly longitudinally extended and measure from  $6.65 \mu$  to  $10 \mu$  in length and from  $7 \mu$  to  $10 \mu$  in breadth. But they are hypertrophied below very young fruiting bodies and measure upto  $12 \mu$  in length and  $13.30 \mu$  in breadth. In places where the young fruiting bodies are developing, involving the hypodermal cells directly, many of these cells become disintegrated and disfigured and may be represented only by conical or irregular appearances. Hypodermal cells below well-developed fruiting bodies are ultimately destroyed by the pathogen and the spaces created are covered over by the fungus mycelium. In some of the hypodermal cells of the region adjoining the fruiting bodies, the cell contents contract and become rod-shaped, 'H'-shaped (Fig. 2) or coma-shaped (Fig. 3).

Sclerenchyma of the lamina is infected comparatively to a lesser extent. There is no significant change in these cells below very young fruiting bodies. But in severe infections, the complete sclerenchyma patch is pushed aside leaving a cavity (Figs. 4 and 5). Size of the normal sclerenchymatous cells measures  $7.98\mu$  in length and  $6.65\mu$  in breadth and  $26.60\mu$  in length while the normal uninfected cells measure from  $6$  to  $13\mu$  in breadth and upto  $20\mu$  in length. Because of the high degree of infection, separation of some groups of host cells takes place, forming many spaces in the ground tissue (Fig. 8).

Ground tissue of lamina is the badly affected region. The mycelium traverses in the narrow

intercellular spaces of the chlorenchymatous cells. In the early stages of the fungal infection, some of the cells of the ground tissue, which are in direct contact with pathogen, gradually become disintegrated. The cells, adjacent to the infected region, show hypertrophy, measuring upto  $23.94\mu$  in breadth and upto  $20\mu$  in length. Because of the high degree of infection, separation of some groups of host cells takes place, forming many spaces in the ground tissue (Fig. 8).

FIGS. 1-9. Figs. 1, 2 and 3. Epidermal and hypodermal cells in transverse section showing contraction of protoplasm. Fig. 4. Sclerenchymatous patch showing the formation of cavity. Fig. 5. Basal part of a well-developed fruiting body. Fig. 6. Cells of the chlorenchyma in transverse section. Fig. 7. Cells surrounded by intercellular as well as intracellular mycelium. Fig. 8. Formation of the space in the ground tissue. Fig. 9. Showing disorganization of the tannin filled cells.

BC, Burst cell; C, Cavity; CH, Chloroplasts; E, Epidermis; H, Haustorium; I, Intracellular mycelium; IM, Intercellular mycelium; P, Pseudoparenchymatous mass of mycelium; PE, Peridium; S, Spores; SCL, Sclerenchyma; SP, Sporogenous hyphae; ST, Sterile bundle; T, Tannin filled cell.

Due to the infection, the tannin-filled cells contract and thus become irregular in shape. Some of these cells burst off when the infection is high (Fig. 9). Inter as well as intracellular mycelium with knob-like haustoria is also seen around these cells (Figs. 7 and 8).

Chloroplasts are also infected at early and late stages of the fungus infection. They occupy peripheral position (Fig. 6). Sometimes, the cells are observed to be devoid of chloroplasts. The portion of the lamina thus becomes chlorotic and starts drying.

No well-marked effect has been observed on different tissues of vascular bundles. Only some cells of the bundle sheath show hypertrophy.

# GAMETIC STERILITY INDUCED BY GAMMA RAYS IN *LUFFA ACUTANGULA* ROXB.

The intention of the present experiment was to record the amount of sterility as contributed by either the male or the female gamete, or by both, in *M<sub>1</sub>* plants of *Luffa acutangula*, a vegetable plant,

grown from dry seeds irradiated with gamma rays at 20, 30 and 40 kR dose levels.

The pollen grains were stained in Belling's acetocarmine solution and were scored for viability (Table I). In control 94% viability was observed. Results showed an inverse relationship between pollen viability and dose level and this might be due to genetic damage<sup>1</sup> and/or physiological disturbance<sup>2</sup>. Selfing and crossing operations between treated and untreated plants were classified under four categories, viz., (A) control selfed, (A) *M<sub>1</sub>* × control, (C) control × *M<sub>1</sub>* and (D) *M<sub>1</sub>* selfed. Each category was repeated ten times and then the mean values of three characters, namely total number of seeds per fruit, percentage of seed germination and seedling survival per fruit were recorded (Table I). Comparison among the four categories with respect to the three above characters showed that (A) control selfed and (D) *M<sub>1</sub>* selfed possessed higher and lower values, respectively, than both the respective reciprocal crosses. Statistical analysis (analysis of variances) showed that the reciprocal crosses (B and C) have nearly equal values whereas AB, AC, BD and CD values are significant at 1% level of probability for all characters at different exposures. The observations are similar to those of *L. cylindrica*<sup>3</sup> with reference to the significant and non-significant values of the respective crosses.

From the above results it is evident that both the gametes of *M<sub>1</sub>* plants of *L. acutangula* contribute equally and significantly towards total sterility, irrespective of one being numerically superior, more radiosensitive<sup>4</sup>, less viable<sup>5</sup> and subjected to

TABLE I  
Gametic damage as induced by gamma rays on *L. acutangula*

| Dose in kR | Category                          | % pollen fertility | Seeds/fruit No. S.E. | % Seed germination | Seedling/fruit No. S.E. |

### A NEW MENACE TO "KAMADHENU", A HYBRID GRASS IN KARNATAKA

KAMADHENU, a new hybrid grass (*Pennisetum purpureum* Schum.  $\times$  *Pennisetum typhoides* Stapf.) is a recent release of University of Agricultural Sciences, Bangalore, and claimed to be a very

promising fodder source. It was released during 1972 and at a time when it is just getting popular with cultivators, it seems to have received a serious setback during 1974 due to widespread incidence of a fungal disease. There are reports from around Bangalore and Dharwar of total failure of the crop after first cutting, due to this disease. In view of the importance of this valuable hybrid in Agriculture and seriousness of this new malady, preliminary investigations were conducted to study the nature and cause of the disease.

Examination of the plants in different stages of the development of the disease has revealed that all the above-ground plant parts are involved.

On newly infected leaves, small reddish brown spots, surrounded by a yellow halo, appear. As these spots enlarge longitudinally and to a lesser extent in breadth, the centre of the spots becomes straw coloured with reddish brown margin. Majority of the spots have sharp ends resembling

FIGS. 1-3, 4 A-B

typical "eye-spots" (Fig. 1). Individual lesions on the leaves measure 0.5-1 cm in length and 3-5 mm in breadth. When such spots coalesce, they may measure upto 10-15 cm in length. Such coalesced spots do not have any well-defined shape or margin. In severe cases leaves show blighted appearance. Similar symptoms are found on leaf-sheaths, culms and at the collar region (Fig. 2). After first cutting, when the new tillers are emerging, they are badly damaged at the collar region resulting in death of the plants. Rotting at the collar region is not uncommon (Fig. 3).

Tissue isolations for the pathogen were made from the necrotised areas from leaves, culms and collar regions separately and all these isolations invariably yielded pure cultures of a fungus akin to *Helminthosporium* sp. Incidentally, it was noticed that cultures from such tissue isolations, when kept continuously in darkness in the incubator, did not sporulate. However when the same were exposed to alternate light and darkness, there was heavy sporulation.

A week old sporulating culture was successfully used to produce artificial infection on healthy plants of Kamadhenu grass and its parents, i.e., *P. purpureum* and *P. typhoides*. Typical symptoms were noticed on the leaves and leaf sheaths after 3 days of inoculation.

The fungus makes a fairly white growth on potato dextrose agar in the beginning, with age it turns dirty white and finally ashy brown. Abundant sporulation is observed in a week's time on P.D.A.

Conidiophores are straight or flexuous, dark-brown or olivaceous brown measuring  $119-200 \mu \times 2-8 \mu$  (Fig. 4A). Conidia are straight or slightly curved, narrowly ellipsoidal, pale brown to golden brown, measuring  $40-83 \mu \times 9-16 \mu$  (Average  $67 \mu \times 13 \mu$ ) with 5-9 pseudosepta (Fig. 4B).

20 days old culture on P.D.A. also produces abundant chlamydospores, which are usually spherical, intercalary or terminal and in chains.

Comparing the descriptions of the various species of *Helminthosporium* and *Drechslera* recorded on both the parents involved in the development of this hybrid grass, the fungus under consideration has been identified as *Drechslera sacchari* (Butler) Subram. and Jain. Diseased specimens and the culture of the fungus have been deposited in MYSP herbarium and culture collection of University of Agricultural Sciences, Hebbal, with accession No. MYSP 1902 and Culture No. 91 respectively.

Grateful thanks are due to Dr. H. C. Govindu, Senior Professor and Head, Department of Plant

Pathology, Agricultural College, Hebbal, Bangalore, for his encouragement.

### EFFECT OF GAMMA IRRADIATION ON DIPLOID AND TETRAPLOID SEEDS OF *CAJANUS CAJAN* (L.) MILLSP.

SENSITIVITY of diploid and tetraploids to radiations and chemical mutagen treatments as measured by different criteria has been studied by several workers in different crop species<sup>1-3</sup>. In general poor germination and reduced seed fertility are associated with tetraploids and this could be improved by using radiation treatments to a considerable extent<sup>1-3</sup>. The present short communication describes radio-sensitivity of diploid and induced tetraploid seeds of *Cajanus cajan* (L.) Millsp. subjected to different doses of gamma irradiation.

Seeds of Colchicine induced tetraploids of variety T<sub>21</sub> in C<sub>4</sub> generation together with diploid parent were exposed to 0, 15, 20, 30, 40 and 60 Krad of gamma rays in a <sup>60</sup>Co source. After irradiation 100 seeds in each treatment were grown in enamel trays in two replications. Observations on germination (radical initiation) survival (per cent of seeds germinated), seedling height and number of leaves appeared on 21st day after sowing were recorded.

In diploids, germination, survival, seedling height and number of leaves were significantly reduced as the irradiation doses increased (Table I). While in tetraploids initial dose of 15 Krad significantly increased the germination as well as seedling height and the number of leaves. It is likely that low doses of irradiation break dormancy in tetraploids, by stimulating the favourable hormonal activity and cell membrane permeability.

As the irradiation doses increased above 15 Krad in tetraploid, there was a reduction in germination, survival seedling height and number of leaves. The C.D. value for ploidy and 2n x 4n interaction are also summarised in Table I.

TABLE I  
Germination, seedling survival height and number of leaves in diploid and tetraploid *Cajanus cajan* following different doses of gamma rays

| Gamma rays<br>in Krad | Germination<br>(%) |      | Survival<br>(%) |       | Height<br>(cm) |     | Number of<br>leaves |     |

### *Pennisetum polystachyum* (L.) SCHULT. A NEW CHROMOSOMAL RACE

THE genus *Pennisetum* is placed in the tribe Paniceae of Panicoideae—Poaceae. *Pennisetum polystachyum* (L.) Schult. is a polymorphic taxon comprising four chromosomal races— $2n = 36^{4*}$ ,  $2n = 48^2$ ,  $2n = 52^2$  and  $2n = 54^3$ . Hrishik has reported *P. polystachyum* ( $2n = 54$ ) to be a perennial grass while Bor<sup>1</sup> has described it as an annual.

The material for the present study was collected from Coimbatore, and grown in the departmental garden, University of Mysore, Mysore. Young florets of appropriate stages were fixed in 3:1 absolute alcohol-acetic acid solution and stored in 70% alcohol for meiotic studies. Pollen mother cell smears were prepared in acetocarmine. The mitotic chromosomes were studied following Tjio and Levan's<sup>2</sup> technique.

Morphological variations noticed in the present study of three chromosomal races could be positively correlated with the ploidy of the species. The

tetraploid ( $2n = 36$ ) is shorter with dark purplish inflorescence. The hexaploid ( $2n = 54$ ) is tallest with yellowish-brown inflorescence while the new chromosomal race ( $2n = 63$ ) is tall, the inflorescence being reddish-brown in colour.

The fifth chromosomal race of the present study is a new record with unbalanced chromosomes  $2n = 63$ . This has been confirmed by counting the somatic chromosomes from the root tips (Fig. 1).

FIGS. 1-2. Fig. 1. Somatic chromosomes of root tips.  $2n = 63$ .  $\times 665$ . Fig. 2. Meiosis—Diakinesis stage.  $\times 665$ .

This chromosomal race exhibits many abnormalities during meiosis. Multivalents and univalents occur in addition to bivalents during diakinesis (Fig. 2) and Metaphase I. In metaphase I bivalents and multivalents appear on the equatorial plate of the spindle and univalents being at periphery move precociously to the poles. Irregular spindles have been observed in the first and second meiotic divisions. The presence of laggards and their non-inclusion in the telophase nuclei result in micronuclei formation in dyads and tetrads. The irregular comportment of meiotic chromosomes during first and second divisions affect the pollen viability. Stainability tests further revealed that 56% of the pollen to be viable.

Cytoembryological studies of the three chromosomal races  $2n=36$ ,  $2n=54$  and  $2n=63$  indicate that they are facultative apomicts, the mechanism of reproduction being apospory. The details of cytoembryological studies and their reproductive behaviour will be published elsewhere. The observations made here agree with Bor<sup>1</sup> in confirming the species as annual.

Thanks are due to the University Grants Commission, New Delhi, for financial help.

## PLANKTONIC FORAMINIFERA FROM THE BARIPADA BEDS, ORISSA

A DETAILED micropaleontological investigation of the Baripada beds, exposed in the cuttings of the river Burhabalanga, south of the town Baripada ( $21^{\circ} 56' N : 86^{\circ} 44' E$ ) in Mayurbhanj District, Orissa, reveals the presence of a fairly well-preserved foraminiferal assemblage which includes three planktonic species. A comprehensive study pertaining to the systematics, paleoecology and age of foraminifera is in progress and will be published in due course. However, since the planktonic foraminifera are valuable indicators of age, it was considered desirable to report them in the form of present note so that they may illuminate the polemical age of the Baripada beds.

Very little is known about the foraminifera from the Baripada beds. Amongst planktonic forms, only *Globigerina* sp. and *Globorotalia* sp. have been reported by Sarma<sup>1</sup>, Tewari and Awasthi<sup>2</sup>, and Chatterjee<sup>3</sup>. In our material, the planktonic foraminifera occur in very low frequencies and are represented by the following three species: (1) *Globorotalia* sp. indet, (2). *Globigerina* cf. *G. quadriloba* d'Orbigny, (3) *Orbulina suturalis* Brönnimann.

*Orbulina suturalis* makes its first appearance in a limestone band, sandwiched between shale beds of Baripada beds. It is a well-known age marker and was originally described by Brönnimann<sup>4</sup> from the *Globorotalia menardii* zone in the Miocene of Trinidad. A comparative study of the specimens of *O. suturalis* from Baripada was made with the material of this species from Trinidad, kindly sent by Dr. W. Weaver, U.S.A. Our specimens were found identical to the forms from Trinidad in showing the presence of Globigerine-structure as well as faintly developed rounded pores along sutures, separating the Globigerine part from the final chamber, and also sparsely scattered around it, in addition to tiny pores all over the test. The genus *Globigerina* d'Orbigny is represented by a solitary and poorly preserved specimen comparable to *Globigerina quadriloba* d'Orbigny, as illustrated by Bandy<sup>5</sup>. This species was originally described from marly plastic clays (Vindobonian) from Austria. Another genus of planktonic foraminifera is represented by a few specimens of *Globorotalia* Cushman but their poor state of preservation does not permit valid specific identification.

A study of literature indicates that the first appearance of *Orbulina suturalis* is significant in age determination. A majority of foraminiferalogists consider that it first appears during Helvetian stage of Europe and marks the base of Helvetian in Australia and Lillburnian stage in New Zealand, i.e., the first appearance of *O. suturalis* indicates the base of Middle Miocene (personal communications, Dr. D. G. Jenkins, New Zealand, and Dr. N. H. Ludbrook, Australia).

The presence of *Orbulina suturalis* and *Globigerina quadriloba* in the Baripada beds suggests a Middle Miocene age for these beds but in the absence of other marker species, no precise placement within the Middle Miocene could be made.

Thanks are expressed to the Council of Scientific and Industrial Research, New Delhi, for providing financial assistance to one of the authors (P. D.).

# OCURRENCE OF GIANT STOMATA IN CELASTRACEAE AND CONVULVULACEAE

GIANT stomata occur on certain leaves along with the normal stomata<sup>1</sup>. There are a few reports on the occurrence of giant stomata<sup>1-6</sup>. While studying the epidermal features in Celastraceae and Convolvulaceae, we observed abnormally large stomata on the leaves of *Celastrus stylosus* Wall., *Euonymus hamiltonianus* Wall. and *Hippocratea arborea* Roxb. (Celastraceae), and *Ipomoea aquatica* Forsk. (Convolvulaceae).

Stace<sup>1</sup> reported their rare occurrence on the veins and venules. The giant stomata on the midrib and larger veins are in the process of degeneration. However, the ones on the venules show distinct stomatal pores and guard cells comparable to normal stomata. In all the species studied, the giant stomata are almost twice as large as the normal stomata (Table 1, Figs. 1-3). In addition to their size, in *I. aquatica*, the giant stomata can be distinguished from normal, by the presence of two lateral groups of striae (Fig. 3).

FIGS. 1-3. Fig. 1. A portion of lower epidermis of *Hippocratea arborea* in surface view showing a giant stomata (G) along with several stomata of normal size. Figs. 2, 3. A normal stomata from intercostal area and a giant stomata from costal area respectively in surface view from lower epidermis of *Ipomoea aquatica*.

TABLE I

| Species                    | Size of stomata (L × B) in $\mu$ |                | Stomatal frequency per sq. mm | Stomatal index |

## FLUORESCENT ANTIBODY TEST FOR DETECTION OF CITRUS GREENING MYCOPLASMA

In medical sciences the fluorescent antibody technique has been widely used in visualization and identification of bacteria and viruses<sup>2</sup>, and to some extent of mycoplasma<sup>3</sup>. Also, some enzymes and

hormones have been traced in animal tissues by this method<sup>2</sup>. However, very little work has been done in the field of plant pathology<sup>4-6</sup>; none dealing with plant mycoplasmas.

In the present studies, culture of mycoplasma obtained earlier from greening affected citrus plants on PPLO broth<sup>7</sup>, served as antigen. It was concentrated by one cycle of differential centrifugation which involved centrifugation at 10,000 rpm for 20 minutes in a Spinco Ultracentrifuge Model L using phosphate buffer (pH 7.0) to separate the suspended impurities, followed by high speed centrifugation at 25,000 rpm for 120 minutes and dissolving the pellet in a small quantity of M/30 phosphate buffer before final centrifugation at 5,000 rpm for 15 minutes. The concentrated antigen was injected in rabbits intramuscularly thrice at weekly intervals with Freund's adjuvant followed by one intravenous injection without the adjuvant. The blood, collected by bleeding the rabbits after 10 days following the last injection, was allowed to clot at room temperature for four hours and stored overnight in a refrigerator for clot to shrink. The serum was decanted and clarified by low speed centrifugation (7,000 rpm for 15 minutes). The antiserum reacted specifically with the mycoplasma culture and had a titre of 1 : 512.  $\gamma$ -globulins were extracted from antiserum by precipitating with equal volume of 3.2 N ammonium sulphate, dissolving the precipitate in 2 ml *tris*-HCl buffer (pH 7.2) and reprecipitating repeatedly until the precipitate was absolutely white. The  $\gamma$ -globulin solution was dialysed against the same buffer until all the sulphate ions were removed. The pH of the solution was raised to 8.5 with 0.5 M carbonate-bicarbonate buffer (pH 9.0) before stirring it with fluorescein isothiocyanate (FITC), added to the solution at the rate of 50 mg per g of protein, for 4-6 hours in cold (4° C). The preparation was then eluted with the *tris*-HCl buffer on a Sephadex (G-25) column to remove the unconjugated dye (FITC).

For detection of mycoplasma, sections of infected as well as uninfected leaves were cut and flooded with *tris*-HCl buffer. They were then transferred to slides and each one was covered with 1-2 drops of FITC conjugated antiserum. The slides were left in a moist chamber for 8-12 hours at room temperature. After draining off excess conjugated antiserum, the sections were washed with *tris*-HCl buffer and mounted in *tris*-HCl buffered glycerine. When examined under the fluorescent microscope, sections of healthy leaves showed dull blue autofluorescence all over except in the thick walled cells which fluoresced in light green range. In infected leaves, in addition to autofluorescence noted in the healthy leaves, brilliant apple green fluorescence in

the form of dots was observed in phloem cells (Fig. 1). This indicated the presence of mycoplasma.

FIG. 1. Fluorescence photomicrograph of greening affected citrus phloem cell showing mycoplasma-like pathogen (arrows) stained with fluorescein-conjugated antiserum.  $\times$  1,200, approx.

This research was financed in part by a Indian National Science Academy's Grant to one of the authors. SKG.

# TOXIN PRODUCTION BY CORYNEBACTERIUM CASSICOLO AND CURT WIL

A fungus, *Corynebacterium cassicola* (Curt) Wilt, has been found to cause wilt and leaf death in brinjal by producing a necrotic spot syndrome. *C. cassicola* (Curt) Wilt and Curt Wilt is a non-specific wilt pathogen which causes leaf death of many plants including brinjal. The leaf spot phase is a minute water soaked area which expands in size and later develops necrosis, often accompanied by a typical chlorotic halo. Because of the sequential development of symptoms, toxin production by the fungus was suspected. Results of a preliminary investigation are reported herein.

and seven in the same sequence. All the organic fractions were evaporated to dryness. The individual fractions from the CF and mycelium were water insoluble and, therefore, suspended in water and used for biological activity employing the leaf spot bioassay. The results of the bioassay are given in Table I.

The earliest symptom was water soaking at the point of application on the lower surface of leaf. Eventually there developed on the upper surface of the leaves a necrotic lesion with a chlorotic halo, simulating the natural lesion. This stage is referred to as the complete symptom. Out of all the fractions benzene fraction and ethylacetate fractions gave most biological activity. The appearance of necrotic symptoms with fractions from the fungus

TABLE I

Effect of various fractions of the culture filtrate and mycelium (CF) of *C. cassicola* on brinjal leaves

| Solvent fraction | Time required for the symptom development |          |  |          |

| Petroleum ether  | 65-72 hrs.                                | ..       | Chlorosis is not seen<br>Necrosis noticed after<br>72 hrs. | ..       |
| Benzene          | 2-3 min.                                  | 2-5 mts. | 48 hrs.  | 48 hrs.  |
| Chloroform       | 68 hrs.                                   | 48 hrs.  | 96 hrs.  | 72 hrs.  |
| Ethyl acetate    | 36 hrs.                                   | 36 hrs.  | 72 hrs.  | 72 hrs.  |

The fungus was grown in still liquid cultures, the medium consisting of 3.3% sucrose, 0.33%  $\text{KH}_2\text{PO}_4$ , 0.17%  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ , and 0.1% casein hydrolysate adjusted to pH 5.5. Cell free culture filtrate (CF) of 10-day old cultures were obtained by filtration through Whatman No. 1 filter paper. Immersing petioles of detached leaves and cut shoots of brinjal (cut leaf/shoot bioassay) in CF induces flaccidity of leaves, and wilt in cut shoots in 4 hours. Cut shoots of tobacco, *Solanum nigrum* L. and castor also showed similar symptoms when kept in CF. Necrotic spots developed in 4 days at the points of application of CF on the lower surface of detached brinjal leaves incubated in humid petri plates (leaf spot bioassay).

The CF was concentrated *in vacuo* and precipitated with ethanol. The supernatant was serially extracted with petroleum ether, benzene, chloroform and ethyl acetate. The fractions were later evaporated to dryness. Freshly harvested mycelial mats were washed thoroughly with glass distilled water and blotted with Whatman No. 1 filter papers. These mats were later extracted with

and CF indicates that the toxic metabolites are endogenous and are secreted into the medium during its active growth phase. Appearance of wilt symptoms in cut shoots of brinjal and certain other hosts and production of necrotic spots with toxic fractions on leaves of brinjal and certain unrelated hosts suggest that the substance involved is of non-specific phytotoxic nature, which is probably related to the ability of the fungus to infect a large variety of plants. Further work on toxin purification is in progress.

THE MORPHOLOGY OF *HEXAMITUS*  
*KAKATHIAE* N. SP. FROM GARDEN LIZARD  
*CALOTES VERSICOLOR*

THE investigation of the intestinal Protozoans of the lizards of Warangal, A.P., revealed an interesting flagellate belonging to the genus *Hexamitus* Dujardin<sup>1</sup>. This genus belongs to the family Hexamitidae Kent and to the order D'plomonadida Wenyon<sup>2</sup>. The infestation was very heavy and found in 85% of the lizards. Extensive work carried out by K. Janaki Devi<sup>3</sup> on Andhra Pradesh reptilian fauna, described a new species from rock lizard, *Calotes nemoricola*. The new species has a typical spherical shape both in living as well as in stained preparations. It measures  $8.0\mu$  to  $8.5\mu$  in diameter. The blepharoplast complex is somewhat interesting (Figs. 2-5). In few forms all the blepharoplasts are fused as a rod-like structure and are placed at the anterior region of the two nuclei (Fig. 1).

FIGS. 1-7. *Hexamitus kakathiae* n. sp. Figs. 1, 4 and 5. Round forms, with four plaques in the nucleus. These figures are drawn from the material fixed in Scheudinn's and stained with iron haematoxylin. Figs. 2 and 3 are showing acronemes to the flagella and are fixed in methylalcohol, stained with Giemsa's. Figs. 6-7 are cysts.

From these complex blepharoplasts three anterior flagella arise, which are subequal in length. In most cases the anterior flagella are ending in acronemes (Figs. 1-4). Axial structures are rod-like and are separated comparatively to a greater extent (Figs. 4-5). However, in a few forms they are

crossed (Figs. 1-2). The axostyles continue beyond the body as the posterior flagella which run close together, and end in acronemes (Figs. 1-3). The two nuclei are round masses, associating to form a single lobe. In most cases these nuclei possess large chromatin granules (Fig. 1). Cysts are very small measuring  $3.5\mu$  in diameter and in almost all cases they are oval in shape (Figs. 6-7).

The genus *Hexamitus* founded by Dujardin<sup>1</sup> includes 3 species. The species *H. xenopi* Fantham and Por<sup>4</sup> and *H. natrix* Matubayashi<sup>5</sup> are reported from opsidan hosts. The third one, *H. kirby*, was reported by Janaki Devi<sup>3</sup> (1957) from rock lizard *Calotes nemoricola*.

The species *H. kirby* Janaki Devi differs in many of the characters from the new species described here from a new host *Calotes versicolor*. *H. kirby* differs in size ( $6.5\mu$ - $13.0\mu$ )  $8.7\mu \times (3.8\mu$ - $10.0\mu)$   $6.6\mu$ . The nuclei are round in shape with central endosome; the six anterior flagella are equal in length; two clear blepharoplasts are at the anterior end of the nuclei; the axial structures possess a chromatic ring at the posterior end.

In view of these differences the parasite under discussion is considered to be a new species and is designated *Hexamitus kakathiae* n. sp. after the place Kakathia, Warangal, A.P.

I wish to express my sincere thanks to Prof. S. S. Qadri, Head, Department of Zoology, Osmania University, Hyderabad, for guidance and encouragement. I am also thankful to Prof. P. Ramchender Rao for Laboratory facilities and encouragement.

# DOWNY MILDNESS IN C. RINOVORCA IN HOT CLIMATE AND CURE

Downy mildew of *C. rinovorca* is a serious disease of this crop in the hot climate of the coastal belt of the Andaman Islands. It is caused by the fungus *Peridermium cinereum* (W.) Sacc. The disease is characterized by the appearance of white, fuzzy growth on the lower surface of the leaves, which later turns brown and necrotic.

## SHORT SCIENTIFIC NOTES

### On the Occurrence of *Blumea heiracifolia* (D. Don) DC. var. *flexuosa* (Cl.) Randeria (Asteraceae) in India

During a recent exploration for the collection of medicinal plants in Chikmagalur district the authors collected near Sirilu village, 40 km from Sringeri (Karnataka State) a taxon identified as *Blumea flexuosa* C.B.Cl.

The revision work of *Randeria* in *Blumea* 10 (1) : 1960, 176-317, on the genus *Blumea* DC. was consulted for determining the nomenclature of this taxon. It was observed that *Randeria*, l.c., p. 249, has reduced this species *flexuosa* C.B.Cl. to a variety under *Blumea heiracifolia* (D. Don) DC. var. *flexuosa* (Cl.) *Randeria*, effecting the new combination also. Further, the occurrence of this plant has been stated to be 'endemic' to Ceylon. This observation of endemism has been based on the herbarium specimens examined by her.

The authors examined the type material at MH and one sheet of *Thwaites* C.P. 19 was observed to be present among this type material and the specimens collected by the authors exactly matched with this specimen. Further, there was one more sheet under *B. flexuosa* collected by R.H. Beddome s.n. (accession No. 27641) with the locality mentioned as South Canara which also matches with the specimen present *Thwaites* C.P. 19.

Gamble has annotated in pencil on this sheet: "I am not sure this may not be *B. crinita*". But *B. crinita* can be easily distinguished from *B. heiracifolia* var. *flexuosa* in not being woolly or silky, having denticulated leaf margins and rounded leaf bases (*Randeria*, l.c., p. 251).

The collection of our specimens from Sirilu village and the presence of a sheet in MH from South Canara, both of which match with the type material *Thwaites* C.P. 19 present at MH, corroborates the occurrence of this taxon as mentioned by Gamble in the *Flora of the Presidency of Madras*, p. 481 (repr. ed. 1967) under *B. flexuosa*, as occurring in "Western Ghats, hills of Mysore at 3,500 ft., Sispara in Nilgiris about 6,000 ft., hills of Travancore at 6,000 ft".

While *Randeria* has made every attempt to examine all available sheets in the various herbaria, it is quite possible that she has missed the sheets from South India (since no reference has been made in the revision work) on which Gamble, l.c., p. 481 has based the occurrence of this taxon. Since all the sheets referred to by *Randeria* are from Ceylon,

it has led her to the conclusion that the taxon is endemic to Ceylon.

Our recent collections, supported by a sheet present in MH from South Canara and also the distribution of the taxon as mentioned by Gamble (l.c.) are sufficient to prove that *B. heiracifolia* (Don) DC. var. *flexuosa* (Cl.) *Randeria* is not endemic to Ceylon but also occurs in South India.

*Herbarium specimens examined*: MH: *Thwaites* C.P. 19: one sheet with accession No. 27662 (from Ceylon); R. H. Beddome s.n. (accession No. 27641 from South Canara, 1867). *Yoganarasimhan* 1109, 22-2-1972, flowering, near Sirilu village, ca 1,000 m. fairly common in grasslands of hill tops, deposited at the Herbarium of the Regional Research Centre, Bangalore-11.

The authors are thankful to Mr. Vivekananthan, Botanist, for useful discussion and to the Regional Botanist, Botanical Survey of India, Coimbatore, for permitting to consult the Madras herbarium. Thanks are also due to the Director, Central Council for Research in Indian Medicine and Homoeopathy, New-Delhi and Officer-in-Charge, Regional Research Centre, Bangalore, for facilities.

### Discovery of Uraniferous Precambrian Conglomerates at Chikmagalur, Karnataka, India

*Introduction*.—The purpose of this note is to report the discovery of uranium-bearing conglomerates of Precambrian age at Chikmagalur (13° 19' 20" N. 75° 46' 30" E.; Survey of India top-sheet No. 480/15) in Karnataka State, and to briefly describe their geological setting, radioactivity, and mineralogy.

*Geological setting*.—The uraniferous conglomerates occur over a granitic-migmatitic basement, and grade upwards to pebbly quartzite, grit, arkose, and quartzite. This sequence is followed by a second zone of conglomerates, and by massive mafic metavolcanic rocks, in some of which pillow structures can be recognised.

*Uranium content*.—Surface samples of the conglomerates have assayed upto 0.13%  $U_3O_8$ , and core samples from boreholes drilled to a depth of 106 metres analyse upto 0.21% uranium. 90% of the uranium is in a leachable state.

**Distribution.**—The uraniferous conglomerates occur as five distinct ribbon-shaped bands or beds, each 5 km long.

**Mineralogy.**—The radioactive minerals in the conglomerates are pitchblende, monazite, and zircon. The other interesting constituents are chalcopyrite, covellite, rammelsbergite, pyrite, siderite, ilmenite, rutile, leucoxene, and magnetite. The common minerals include white and grey quartz pebbles (1 to 3 cm in diameter) embedded in a quartz-rich matrix, and some ferromagnesian assemblages.

**Conclusion.**—Preliminary studies suggest that the uraniferous conglomerates of Chikmagalur are comparable to the well-known uranium-rich Precambrian quartz-pebble conglomerates of Blind River in Canada, and the Witwatersrand in South Africa. The results of detailed investigations currently in progress will be published elsewhere.

I am grateful to Dr. G. R. Udas, Director, Atomic Minerals Division, for suggesting the study.

# Identification of Chlorinated Hydrocarbon Pesticides on T.L.C. Plates Using Modified Wood's Reagent

Wood<sup>1</sup> described the use of a mixture of bromophenol blue and silver nitrate for the detection of chloride ion on paper chromatograms. Abbott, Egan and Thomson<sup>2</sup> used this reagent for the detection of chlorinated hydrocarbon pesticides on T.L.C. plates. However the limits of detectability were not reported. Their method of detection involved several steps and there was difficulty in handling the plates at 105° C.

A modified Wood's reagent using ammonia vapour exposure, developed in this laboratory, eliminates these difficulties and facilitates detection of chlorinated pesticides at levels less than 1 µg. The method is as follows :

T.L.C. plates are prepared using prewashed silica gel G with a layer thickness of 250 µ. Chromatograms of Aldrin, Dieldrin, Endrin, Thiodan and D.D.T. with different concentrations are developed using cyclo-hexane as solvent. After development the plates are dried at room temperature and sprayed with the modified Wood's reagent (90 ml of 0.05% bromophenol blue dissolved in acetone plus 10 ml of 2% aqueous silver nitrate solution). They are then exposed to ammonia vapour for 15 minutes in a sealed tank. Blue spots on purple background

are observed. The limits of detectability of various pesticides are presented in Table I.

TABLE I

| Pesticide          | Lowest limit of detectability (µg) | Value of $\lambda_{max}$ (nm)            |
|--------------------|------------------------------------|--|
| Aldrin             | 0.5                                | 0.22                                     |
| Dieldrin           | 0.5                                | 0.29                                     |
| Endrin             | 0.5                                | 0.31                                     |
| Thiodan            | 3.0                                | 0.38                                     |

## *Archipsocus* sp. (Archipsocidae: Psocoptera), A New Pest of Citrus from India\*

Some Mandarin (*Citrus reticulata*) trees were found severely attacked by psocid, *Archipsocus* sp. during the surveys of citrus orchards in Coorg District during September–October 1972 and 1973. Nymphs and adults gregariously feed on the foliage and shoots by inhabiting within the silken webs formed by them. Occasionally the colonies extend upto the main branches. Affected twigs turn yellow and chlorotic. In severe cases the leaves shed off and twigs and branches die out. About 128 insect pests, so far, have been reported to attack *Citrus* spp. in India<sup>1</sup>. This is the first record of this insect pest on citrus and as such is an addition to the above list.

Thanks are due to Dr. G. S. Randhawa, Director, Indian Institute of Horticultural Research, for encouragement and to Dr. R. G. Fennah, Director, British Museum, London, for identification of the pest.

## SHORT SCIENTIFIC NOTES

### On the Occurrence of *Blumea heircifolia* (D. Don) DC. var. *flexuosa* (Cl.) Randeria (Asteraceae) in India

During a recent exploration for the collection of medicinal plants in Chikmagalur district the authors collected near Sirilu village, 40 km. from Sringeri (Karnataka State) a taxon identified as *Blumea flexuosa* C.B.Cl.

The revision work of Randeria in *Blumea* 10 (1) : 1960, 176-317, on the genus *Blumea* DC. was consulted for determining the nomenclature of this taxon. It was observed that Randeria, *l.c.*, p. 249, has reduced this species *flexuosa* C.B.Cl. to a variety under *Blumea heircifolia* (D. Don) DC. var. *flexuosa* (Cl.) Randeria, effecting the new combination also. Further, the occurrence of this plant has been stated to be 'endemic' to Ceylon. This observation of endemism has been based on the herbarium specimens examined by her.

The authors examined the type material at MH and one sheet of Thwaites C.P. 19 was observed to be present among this type material and the specimens collected by the authors exactly matched with this specimen. Further, there was one more sheet under *B. flexuosa* collected by R.H. Beddome s.n. (accession No. 27641) with the locality mentioned as South Canara which also matches with the specimen present Thwaites C.P. 19.

Gamble has annotated in pencil on this sheet: "I am not sure this may not be *B. crinita*". But *B. crinita* can be easily distinguished from *B. heircifolia* var. *flexuosa* in not being woolly or silky, having denticulated leaf margins and rounded leaf bases (Randeria, *l.c.*, p. 251).

The collection of our specimens from Sirilu village and the presence of a sheet in MH from South Canara, both of which match with the type material Thwaites C.P. 19 present at MH, corroborates the occurrence of this taxon as mentioned by Gamble in the *Flora of the Presidency of Madras*, p. 481 (repr. ed. 1967) under *B. flexuosa*, as occurring in "Western Ghats, hills of Mysore at 3,500 ft., Sispara in Nilgiris about 6,000 ft., hills of Travancore at 6,000 ft".

While Randeria has made every attempt to examine all available sheets in the various herbaria, it is quite possible that she has missed the sheets from South India (since no reference has been made in the revision work) on which Gamble, *l.c.*, p. 481 has based the occurrence of this taxon. Since all the sheets referred to by Randeria are from Ceylon,

it has led her to the conclusion that the taxon is endemic to Ceylon.

Our recent collections, supported by a sheet present in MH from South Canara and also the distribution of the taxon as mentioned by Gamble (*l.c.*) are sufficient to prove that *B. heircifolia* (Don) DC. var. *flexuosa* (Cl.) Randeria is not endemic to Ceylon but also occurs in South India.

*Herbarium specimens examined*: MH: Thwaites C.P. 19; one sheet with accession No. 27662 (from Ceylon); R. H. Beddome s.n. (accession No. 27641 from South Canara, 1867). Yoganarasimhan 1109, 22-2-1972, flowering, near Sirilu village, ca 1,000 m. fairly common in grasslands of hill tops, deposited at the Herbarium of the Regional Research Centre, Bangalore-11.

The authors are thankful to Mr. Vivekananthan, Botanist, for useful discussion and to the Regional Botanist, Botanical Survey of India, Coimbatore, for permitting to consult the Madras herbarium. Thanks are also due to the Director, Central Council for Research in Indian Medicine and Homoeopathy, New-Delhi and Officer-in-Charge, Regional Research Centre, Bangalore, for facilities.

### Discovery of Uraniferous Precambrian Conglomerates at Chikmagalur, Karnataka, India

*Introduction*.—The purpose of this note is to report the discovery of uranium-bearing conglomerates of Precambrian age at Chikmagalur (13° 19' 20" N. 75° 46' 30" E.; Survey of India top-sheet: No. 480/15) in Karnataka State, and to briefly describe their geological setting, radioactivity, and mineralogy.

*Geological setting*.—The uraniferous conglomerates occur over a granitic-migmatitic basement, and grade upwards to pebbly quartzite, grit, arkose, and quartzite. This sequence is followed by a second zone of conglomerates, and by massive mafic metavolcanic rocks, in some of which pillow structures can be recognised.

*Uranium content*.—Surface samples of the conglomerates have assayed upto 0.13%  $U_3O_8$ , and core samples from boreholes drilled to a depth of 106 metres analyse upto 0.21% uranium. 90% of the uranium is in a leachable state.

**Distribution.**—The uraniferous conglomerates occur as five distinct ribbon-shaped bands or beds, each 5 km long.

**Mineralogy.**—The radioactive minerals in the conglomerates are pitchblende, monazite, and zircon. The other interesting constituents are chalcocopyrite, covellite, rammelsbergite, pyrite, siderite, ilmenite, rutile, leucocene, and magnetite. The common minerals include white and grey quartz pebbles (1 to 3 cm in diameter) embedded in a quartz-rich matrix, and some ferromagnesian assemblages.

**Conclusion.**—Preliminary studies suggest that the uraniferous conglomerates of Chikmagalur are comparable to the well-known uranium-rich Precambrian quartz-pebble conglomerates of Blind River in Canada, and the Witwatersrand in South Africa. The results of detailed investigations currently in progress will be published elsewhere.

I am grateful to Dr. G. R. Udas, Director, Atomic Minerals Division, for suggesting the study.

#### Identification of Chlorinated Hydrocarbon Pesticides on T.L.C. Plates Using Modified Wood's Reagent

Wood<sup>1</sup> described the use of a mixture of bromophenol blue and silver nitrate for the detection of chloride ion on paper chromatograms. Abbott, Egan and Thomson<sup>2</sup> used this reagent for the detection of chlorinated hydrocarbon pesticides on T.L.C. plates. However the limits of detectability were not reported. Their method of detection involved several steps and there was difficulty in handling the plates at 105° C.

A modified Wood's reagent using ammonia vapour exposure, developed in this laboratory, eliminates these difficulties and facilitates detection of chlorinated pesticides at levels less than 1 µg. The method is as follows:

T.L.C. plates are prepared using prewashed silica gel G with a layer thickness of 250 µ. Chromatograms of Aldrin, Dieldrin, Endrin, Thiodan and D.D.T. with different concentrations are developed using cyclo-hexane as solvent. After development the plates are dried at room temperature and sprayed with the modified Wood's reagent (90 ml of 0.05% bromophenol blue dissolved in acetone plus 10 ml of 2% aqueous silver nitrate solution). They are then exposed to ammonia vapour for 15 minutes in a sealed tank. Blue spots on purple background

are observed. The limits of detectability for various pesticides are given in Table I.

TABLE I

| Pesticide      | Lowest Detectability (µg) | Limit of detection (1:4 to 1:1) |
|----------------|---------------------------|---------------------------------|
| Aldrin         | 0.5                       | 0.05                            |
| Dieldrin       | 0.5                       | 0.25                            |
| Endrin         | 0.5                       | 0.31                            |
| Thiodan        | 3.0                       | 0.38                            |
| OP, DPT and PP | 0.6 µg/in                 | 0.75 for OP isomer              |
| DDT            | technical DDT             | 0.75 for PP isomer              |

### Test of Baermann Technique for the Recovery of Infective Larvae of *Cooperia curticei* from Faecal Pellets

In ecological and epidemiological studies of strongyle nematodes the recovery of the infective larvae from cultures of faecal pellets may be necessary. Infective larvae are generally recovered from faecal pellets by Baermann technique; but the efficiency of this technique may depend on the bulk and physical conditions of the faecal culture. A test of this technique was done with known number of *Cooperia curticei* infective larvae reared in the laboratory<sup>2</sup>. Infective larvae were counted individually in five samples each in 4 range groups, covering the range 0-50, 100-200, 300-500, and 800-1200 larvae respectively. In each sample, the larvae were allowed to remain for half an hour on 10g parasite-free normal faecal pellets. The material was then allowed to remain immersed in warm water (40°C) in Baermann funnel for two days. At 24 and 48 hours interval, 25 ml of water was drawn off from the bottom and larvae present in the sediment and washing of the pipettes and tubes were counted microscopically.

The percentage recovery of the infective larvae from each sample ranged from 50.0 to 66.3%. An analysis of variance was carried out on percentage recovery after arcsin transformation of the percentage to stabilise the variance. The result:  $p < 0.05$  suggests that the recovery efficiency of the technique is independent of the numbers of infective larvae present within the range tested.

### *Albizzia lebbek*—A New Host for Citrus White Fly (*Dialeurodes citri* Ashmead)

During July 1974 a large number of adults as well as nymphs of citrus white fly (*Dialeurodes citri* Ashmead) were found feeding on small seedlings of *Albizzia lebbek* which is grown as wind

break near the citrus orchards at Punjab Agricultural University, Ludhiana. Nature of damage was similar to that reported on citrus by Pruthi and Batra<sup>1</sup>.

The pest has been reported to feed on 42 different plant hosts which include different species of citrus and deciduous plants by Saini<sup>2</sup> and *A. lebbek* appears to be a new host for *D. citri*.

### Brinjal as a New Host of Yellow Hairy Caterpillar, *Psalis pennatula* (F.) (Lymantriidae: Lepidoptera)

During October, 1974 the younger stage larvae of hairy caterpillar were observed feeding on brinjal crop at the Entomological Farm, Punjab Agricultural University, Ludhiana. The larvae were collected and reared in the laboratory on brinjal leaves. The adults which emerged were identified as *Psalis pennatula* (F.). The survey of the literature revealed its earlier record on paddy, *Cholam*, ragi, sugarcane, grasses, cowpea and truck. Thus it appears to be the first record of this insect on brinjal.

The authors are grateful to Prof. O. S. Bhandra for providing the facilities and to Dr. G. S. Sandhu, Entomologist (Research), for identification of the insect.

(MS. 50)

The temperature dependence of light output of the ZnO-MnO<sub>2</sub> phosphor has been studied. The phosphor thus obtained exhibits peak light output at 200°C. The intensity of the emission is maximum at 200°C. The temperature dependence of the intensity of the emission is studied. The relationship between the intensity of the emission and the temperature is studied.

### INTRODUCTION

THE temperature dependence of electroluminescent brightness is an important characteristic of Deslaur effect and is of much help for understanding the nature of trap levels which exert remarkable influence on the emission characteristics of electroluminescent phosphors. Deslaur studied the behaviour of ZnO, ZnS type phosphors and observed that the threshold voltage of excitation falls as the temperature is lowered. Later works due to Gobrecht, Roberts, Hults, Neumark, Matz, Thornton and Harker in this direction are also remarkable. Oskot<sup>1</sup> has observed that the emission characteristics are mainly concentrated in yellow-orange region.

### EXPERIMENTAL

The zinc oxide is activated with trace quantities (10<sup>-3</sup> g/g) of Mn and fired in nitrogen atmosphere around 1000°C. The phosphor thus obtained shows yellow-orange electroluminescence. For temperature studies, permanent type of electroluminescent cells were formed by dispersing the electroluminescent in Anadite between two conductive but transparent plane parallel mica sheets. The cell so formed was excited at different voltages and frequencies with the help of an audio oscillator cum wide band amplifier unit and the light output was recorded with photomultiplier and ultrasensitive microammeter assembly.

Such a cell was mounted over a copper sheet fitted at the end of a copper rod, about 10" in length and 1" in diameter. The desired temperature was achieved by cooling the rod with the liquid air or by heating it with the help of a cylindrical replaceable heater. The temperature was measured with a copper constantan thermocouple.

### RESULTS AND DISCUSSION

As usual with the electroluminescent of the ZnS-family, the Mn activation in ZnO also gives

the emission in the yellow-orange region. The light output of the phosphor is maximum at 200°C. The intensity of the emission is maximum at 200°C. The temperature dependence of the intensity of the emission is studied. The relationship between the intensity of the emission and the temperature is studied.

The temperature dependence of the intensity of the emission is studied. The relationship between the intensity of the emission and the temperature is studied.

Fig. 1. Brightness-Temperature curves for the electroluminescent ZnO-MnO<sub>2</sub> phosphor at different exciting frequencies and 100 V, 100 Hz, 200 Hz.

This is due to the fact that the rate of recombination of the available time for the recombination of the electrons is decreased, and the energy of the electrons is not enough to make the traps empty. The shift is about 50°C when the electric frequency changes from 200 Hz to 50 Hz. These observations are found in accordance with the observations of No. secondary peaks of electroluminescence observed previously and the effect of electric field.

The temperature dependence of the intensity of the emission is studied. The relationship between the intensity of the emission and the temperature is studied.

\* Present address: Dr. Laxmi Kant Singh, Lecturer in Physics, Kumaon Nohri Institute of Science and Technology, Saharanpur, U.P., India.

# Test of Baermann Technique for the Recovery of Infective Larvae of *Cooperia curticei* from Faecal Pellets

In ecological and epidemiological studies of strongyle nematodosis the recovery of the infective larvae from cultures of faecal pellets may be necessary. Infective larvae are generally recovered from faecal pellets by Baermann technique but the efficiency of this technique may depend on the bulk and physical conditions of the faecal culture. A test of this technique was done with known number of *Cooperia curticei* infective larvae reared in the laboratory<sup>1</sup>. Infective larvae were counted individually in five samples each in 4 range groups, covering the range 0-20, 100-200, 300-500, and 800-1200 larvae respectively. In each sample, the larvae were allowed to remain for half an hour on 10g parasite-free normal faecal pellets. The material was then allowed to remain immersed in warm water (40°C) in Baermann funnel for two days. At 24 and 48 hours interval, 25 ml of water was drawn off from the bottom and larvae present in the sediment and washing of the pipettes and tubes were counted microscopically.

The percentage recovery of the infective larvae from each sample ranged from 50.0 to 66.3%. An analysis of variance was carried out on percentage recovery after arcsin transformation of the percentage to stabilise the variance. The result  $p < 0.05$  suggests that the recovery efficiency of the technique is independent of the numbers of infective larvae present within the range tested.

# *Albizzia lebbek*—A New Host for Citrus White Fly (*Dialeurodes citri* Ashmead)

During July 1974 a large number of adults as well as nymphs of citrus white fly (*Dialeurodes citri* Ashmead) were found feeding on small seedlings of *Albizzia lebbek* which is grown as wind

break near the citrus orchards at Punjab Agricultural University, Ludhiana. Nature of damage was similar to that reported on citrus by Pruthi and Batra<sup>1</sup>.

The pest has been reported to feed on 42 different plant hosts which include different species of citrus and deciduous plants by Saini<sup>2</sup> and *A. lebbek* appears to be a new host for *D. citri*.

# Brinjal as a New Host of Yellow Hairy Caterpillar, *Psalis pennatula* (F.) (Lymantriidae: Lepidoptera)

During October, 1974 the younger stage larvae of hairy caterpillar were observed feeding on brinjal crop at the Entomological Farm, Punjab Agricultural University, Ludhiana. The larvae were collected and reared in the laboratory on brinjal leaves. The adults which emerged were identified as *Psalis pennatula* (F.). The survey of the literature revealed its earlier record on paddy, *Cholam*, ragi, sugarcane, grasses, cowpea and tak. Thus it appears to be the first record of this insect on brinjal.

The authors are grateful to Prof. O. S. Bhandra for providing the facilities and to Dr. G. S. Sandhu, Entomologist (Research), for identification of the insect.

# TEMPERATURE DEPENDENCE OF ELECTROLUMINESCENCE OF ZnO : Mn PHOSPHORS

LAXMI KANT SINGH\* AND HARI MOHAN

*Luminescence Research Laboratories, Physics Department, Allahabad University, Allahabad, India*

## ABSTRACT

The temperature dependence of the electroluminescence around 5900 Å. of ZnO : Mn phosphor have been investigated. The brightness-temperature curves for Mn-emission exhibit peak shift with the rise of excitation frequency, but with rise in voltage only over all intensity is increased. The temperature dependence of threshold excitation frequency obeys the relationship  $\log \nu \text{ (Hz)} = c_1 - c_2/T$ .

## INTRODUCTION

THE temperature dependence of electroluminescent brightness is an important characteristic of Destriau effect and is of much help for understanding the nature of trap levels which exert remarkable influence on the emission characteristics of electroluminophors. Destriau<sup>1</sup> studied the behaviour of ZnO, ZnS type phosphors and observed that the threshold voltage of excitation falls as the temperature is lowered. Later works due to Gobrecht<sup>2</sup>, Roberts<sup>3</sup>, Halsted<sup>4</sup>, Neumark<sup>5</sup>, Mattler<sup>6</sup>, Thornton<sup>7</sup> and Haake<sup>8</sup> in this direction are also remarkable. Osiko<sup>9</sup> has observed that the emission characteristics are mainly concentrated in yellow-orange region.

## EXPERIMENTAL

The zinc oxide is activated with trace quantities ( $10^{-4}$  g/g) of Mn and fired in nitrogen atmosphere around 1000°C. The phosphor thus obtained shows yellow-orange electroluminescence. For temperature studies, permanent type of electroluminescent cells were formed by dispersing the electroluminophor in Araldite between two conductive but transparent plane parallel mica sheets. The cell so formed was excited at different voltages and frequencies with the help of an audio oscillator cum wide band amplifier unit and the light output was recorded with photomultiplier and ultrasensitive microammeter assembly.

Such a cell was mounted over a copper sheet fitted at the end of a copper rod, about 10" in length and 1" in diameter. The desired temperature was achieved by cooling the rod with the liquid air or by heating it with the help of a cylindrical replaceable heater. The temperature was measured with a copper constantan thermocouple.

## RESULTS AND DISCUSSION

As usual with the electroluminophors of the ZnS-family, the Mn activation in ZnO also gives

the emission in yellow-orange region. The emission peak is observed around 5900 Å. We further notice that as the temperature rises, the intensity of yellow-orange emission of Mn increases fast with very little shift in peak position. As the temperature is further increased there is a fall in the intensity due to quenching effect.

## FREQUENCY DEPENDENCE

The brightness *versus* temperature curves exhibit that as the excitation frequency is increased, the emission peak shifts to high temperature (Fig. 1).

FIG. 1. Brightness vs. Temperature curves for the electro-luminophor ZnO : Mn excited by different exciting frequencies at fixed voltage near 600 V.

This is due to the fact that with increased frequency the available time for the exhaustion of the trapped electrons is decreased, requiring higher thermal energy to make the traps empty<sup>5</sup>. This shift is about 80°C when the excitation frequency changes from 200 c/s to 5 kc/s. These observations are found in accordance with the well-known facts<sup>10,11</sup>. No secondary peaks on temperature scale are observed probably due to absence of deeper traps.

The temperature effect at different voltages of excitations were tried. Plots of  $\log \nu \text{ (Hz)}$  vs.

\* Present address : Dr. Laxmi Kant Singh, Lecturer in Physics, Kamla Nehru Institute of Science and Technology, Sultanpur (U.P.), India.

1/T (Fig. 2) gave straight lines obeying the relationship<sup>12</sup>  $\log \nu \text{ (Hz)} = c_1 - c_2/T$ . The slope of these straight lines decreased with the rise of

peratures. This type of behaviour at low temperature may be correlated with the decrease in trap depth.

FIG. 2. Dependence of threshold frequencies of excitation with the temperature for ZnO : Mn/. excitation voltages, which means, higher threshold frequencies are required at the lower voltages for excitation.

**Voltage Dependence.**—Increase in voltage enhances the brightness (Fig. 3) at different temperatures but no peak shift is observed. This peak is found around 20°C when the excitation field frequency is kept at 1.5 kc/s. At 600 volts, the brightness is enhanced considerably at low tem-

## 2-HYDROXY-3,5-DICHLOROACETOPHENONE OXIME AS AN ANALYTICAL REAGENT : GRAVIMETRIC DETERMINATION OF COPPER, NICKEL AND COBALT

KEEMTI LAL AND S. P. GUPTA

*Chemical Laboratories, D.N. College, Meerut-2*

### ABSTRACT

2-Hydroxy-3,5-Dichloroacetophenone Oxime (HDCAO), has been found to be a good reagent for gravimetric estimation of copper, nickel and cobalt and for their separation from other ions. The composition of the complexes is 1:2 as determined by modified continuous variation method.

OXIMES have been used as analytical reagents for the gravimetric as well as spectrophotometric determination of a number of metal ions<sup>1-3</sup>. In an earlier communication<sup>4</sup>, conductometric, potentiometric, micro-analysis and I.R. spectral

studies were reported for these metal complexes. The reagent has now been successfully employed for the gravimetric determination of copper, nickel and cobalt and their separation from a number of other ions.

# EXPERIMENTAL

2-Hydroxy-3,5-Dichloroacetophenone Oxime (HDCAO) was prepared as described earlier<sup>1</sup>. An ethanolic solution of the ligand was employed. Solutions of copper, nickel and cobalt salts were prepared from B.D.H. (A.R.) samples and standardized gravimetrically. Solutions of other ions were prepared from Reagent Grade samples. Systronic pH meter type 322 was used for pH measurement.

**Determination of Copper.**—The thiocyanate method suffers from the disadvantage of a low conversion factor and takes a long time (~6 hr) for complete precipitation. Salicylaldoxime and *o*-hydroxyacetophenone oxime complexes are somewhat soluble in ethanol. As a consequence, excess of reagent which gets precipitated is difficult to wash. But the complexes of HDCAO with copper, nickel and cobalt are insoluble in 60% ethanol and the excess of reagent that is precipitated can easily be washed. The pH ranges for complete precipitation and also separation of copper from nickel and cobalt are wider as compared to salicylaldoxime and *o*-hydroxy acetophenone oxime.

The pH of an aqueous solution (~100 ml) containing about 10 mg of copper was adjusted to known value using acetic acid and ammonia buffer. The solution was heated to 60–70°C and treated with an ethanolic solution of HDCAO (0.5%) dropwise (about twice the theoretical value) with constant stirring. The buff coloured precipitate was digested on a water bath for about 30 min. It was filtered while hot, through a sintered glass crucible (G-4) and washed with hot water. The precipitate was finally washed several times with 50% ethanol and was dried at 100–120°C to constant weight. It has been found that copper can be quantitatively determined in the pH range 3.0–10.0 although the precipitation starts at pH 2.0. The conversion factor (metal/metal complex) is 0.1267.

**Study of Interference.**—By suitable adjustment of pH, excess of the following cations (five to ten times) could be tolerated: Fe (II), Fe (III), Bi (III), Sb (III), As (III) (at pH 3.0); Ni (II), Co (II), Zn (II), Cd (II), Mo (VI), Hg (II), Mn (II), Mg (II), W (VI), UO<sub>2</sub> (II) (at pH 4.0). About 10–100 times of molar excess of several anions could be tolerated at pH 4.0 (PO<sub>4</sub><sup>3-</sup>, Cl<sup>-</sup>, Br<sup>-</sup>, I<sup>-</sup>, F<sup>-</sup>, B<sub>4</sub>O<sub>7</sub><sup>2-</sup>, SO<sub>4</sub><sup>2-</sup>, S<sub>2</sub>O<sub>3</sub><sup>2-</sup> and tartrate).

**Determination of Copper in Alloys.**—A known amount of the alloy (brass, aluminium-bronze, manganese-bronze) was dissolved in conc. HNO<sub>3</sub>. The excess of acid was evaporated. The stannic oxide was removed by filtration. Copper was determined in the filtrate at pH 3.0, as described

earlier. The other ions did not interfere. It has been found that the percentage of copper obtained in different alloys using this method agrees with the reported values within experimental errors.

**Determination of Nickel.**—It has been found that HDCAO can precipitate (green) nickel quantitatively in about 100 ml solution containing 8 mg nickel ion in the pH range 5.0–9.0 using acetic acid and ammonia buffer for adjusting the pH. The experimental procedure for the precipitation of nickel was the same as described in the case of copper. The conversion factor is 0.1182.

**Study of Interference.**—Wherever possible, the interfering ions have been masked with suitable masking agents, e.g., Fe (III), Sb (III), Bi (III) by tartaric acid (1 gm). In some cases, the interference has been removed by changing the pH of the mixed solution, e.g., cations like Zn (II), Mn (II) (at pH 5.5); Cd (II), UO<sub>2</sub> (II), Mg (II), Mo (VI), W (VI), Hg (II) (at pH 6.0); Fe (III), Sb (III), Bi (III), As (III) (at pH 7.5) (from 5–10 times excess) and sufficiently large excess of anions like PO<sub>4</sub><sup>3-</sup>, Cl<sup>-</sup>, Br<sup>-</sup>, I<sup>-</sup>, F<sup>-</sup>, SO<sub>4</sub><sup>2-</sup>, S<sub>2</sub>O<sub>3</sub><sup>2-</sup>, B<sub>4</sub>O<sub>7</sub><sup>2-</sup> and tartrate (at pH 6.0).

**Determination of nickel in alloys.**—A known amount of the alloy (aluminium-bronze, high tensile brass and coin) was dissolved in conc. HNO<sub>3</sub> and the tin removed as SnO<sub>2</sub>. The copper in the filtrate was first determined at pH 3.0 and the nickel was then estimated by raising the pH of the filtrate to 8.0.

**Determination of Cobalt.**—HDCAO has also been found to precipitate (orange) cobalt quantitatively. The pH of cobalt solution about 100 ml containing 9 mg of cobalt was adjusted to 8–9 using acetate-borax buffer. The experimental procedure for the precipitation of cobalt was the same as described in the case of copper. The precipitate was washed with hot water and finally with 25% alcohol. The conversion factor was 0.1186.

**Study of Interference.**—The cations Zn (II), Mn (II), Mg (II), Cd (II), As (III), Mo (VI), W (VI) (five to seven times) and excess of the anions Cl<sup>-</sup>, Br<sup>-</sup>, I<sup>-</sup>, SO<sub>4</sub><sup>2-</sup>, S<sub>2</sub>O<sub>3</sub><sup>2-</sup> and tartrate do not interfere in the determination of cobalt at pH 7.5.

From the solution, containing both copper and cobalt, the copper was precipitated as described earlier at pH 3.0 and from the filtrate cobalt was precipitated by the addition of more reagent and adjusting pH to 7.5.

**Accuracy of the estimation.**—Copper, nickel (5–50 mg) could be estimated with an accuracy of ±0.3% while in the case of cobalt (10–50 mg) the percentage error was ±0.4%. At lower concentrations of the metals (3–5 mg) the percentage error was about 5% higher.

The composition of the complexes as determined above and also by using modified continuous variation method<sup>6</sup> is 1:2.

#### ACKNOWLEDGEMENT

## ZIRCONIUM(IV) COMPLEXES WITH MULTIDENTATE SCHIFF BASES

N. S. BIRADAR, (Miss) A. L. LOCKER AND V. H. KULKARNI

Department of Chemistry, Karnatak University, Dharwar 580003, India

#### INTRODUCTION

IN the previous papers we showed that zirconium exhibits coordination numbers five and eight when complexed with bidentate and tetradentate Schiff bases<sup>1-3</sup>. Macarovici *et al.*<sup>4</sup> have demonstrated that zirconium forms complexes of coordination number six with Schiff bases derived from benzidine. There is not much information on the zirconium (IV) complexes with multidentate Schiff bases<sup>4-5</sup>.

In this paper we report the synthesis and spectral study of a few zirconium (IV) complexes with multidentate Schiff bases shown below.

#### EXPERIMENTAL

Zirconyl chloride used for preparing the complexes was of Fluka make. *p,p'*-Diaminodiphenyl

sulphide was prepared by the known method<sup>6</sup>. Schiff bases were prepared by Biradar's method<sup>7</sup>.

Zirconyl chloride in methanol was treated with a slight excess of Schiff base in the same solvent. This mixture was refluxed for 2-3 hours on water bath. The complex separated out was filtered and washed free from the reagent with methanol, then with ether and dried in vacuum. The complexes were analysed for zirconium, nitrogen and chloride contents<sup>8</sup>.

#### RESULTS AND DISCUSSION

It is evident from the elemental analysis (Table I) that these bases form the complexes of 1:1 stoichiometry.

**Infrared Spectra.**—Infrared spectra of the Schiff bases and complexes in Nujol mulls have been taken with a Perkin Elmer 137 B spectrometer. The strong band in the region 1618-1613 cm<sup>-1</sup> attributable to the C=N stretching is found in the region 1640-1626 cm<sup>-1</sup> in these zirconium (IV) complexes. The shift towards higher frequency indicates coordination through the azomethine nitrogen.

The broad weak band in the region 2800-2700 cm<sup>-1</sup> due to the intramolecular hydrogen bonded OH is not observed in the complexes and the band due to the phenolic C-O in the region 1280-1270 cm<sup>-1</sup> is found around 1300 cm<sup>-1</sup>. These observations show that the hydroxy groups of the base are involved in the bond formation. Analogous observations have been made by Kovacic<sup>9a</sup> in copper (II) Schiff base complexes and Marvel *et al.*<sup>9b</sup>.

It has been established that when a compound contains M=O, the infrared spectrum shows a narrow intense band in the region 1100-800 cm<sup>-1</sup> whereas a broad intense band in the corresponding region indicates the presence of a polymeric M-O-M

TABLE I  
Elemental analysis of the complexes

| Lig. No. | Comp. No. | Empirical formula   | % Zr          | % N         | % Cl          |
|----------|-----------|---|---------------|-------------|---------------|
| I        | 1         | (C <sub>16</sub> H <sub>14</sub> N <sub>2</sub> O <sub>2</sub> ) ZrCl <sub>2</sub>  | 20.88 (21.30) | 6.13 (6.54) | 15.85 (16.54) |
| II       | 2         | (C <sub>20</sub> H <sub>13</sub> N <sub>2</sub> O <sub>2</sub> ) ZrCl <sub>2</sub>  | 19.20 (19.60) | 6.00 (6.42) | 15.02 (15.26) |
| III      | 3         | (C <sub>20</sub> H <sub>13</sub> N <sub>2</sub> O <sub>2</sub> ) ZrCl <sub>2</sub>  | 16.20 (16.52) | 5.02 (5.07) | 12.00 (12.86) |
| IV       | 4         | (C <sub>20</sub> H <sub>13</sub> N <sub>2</sub> O <sub>2</sub> ) ZrCl <sub>2</sub>  | 16.55 (16.08) | 7.36 (7.40) | 12.80 (12.51) |
| V        | 5         | (C <sub>20</sub> H <sub>13</sub> SN <sub>2</sub> O <sub>2</sub> ) ZrCl <sub>2</sub> | 15.40 (15.65) | 5.07 (4.79) | 12.03 (12.10) |

chain<sup>10</sup>. Patel and coworkers<sup>11,12</sup> have assigned a narrow intense band around 980 cm<sup>-1</sup> to Zr=O stretch in zirconium complexes. Biradar *et al.*<sup>3</sup> have assigned the band around 917 cm<sup>-1</sup> to Zr=O stretch in zirconyl (II) Schiff base complexes. These observations and the comparative study of the infrared spectra of the Schiff bases and the complexes suggest that these zirconium complexes do not contain either Zr=O or Zr-O-Zr moiety in them.

The base I is sterically favourable and can encompass the metal ion strainlessly<sup>12</sup>, preferring *cis* configuration<sup>13</sup>. The base II is a more rigid tetradentate as the CH<sub>2</sub>-CH<sub>2</sub> is replaced by a phenyl ring. This too prefers to have *cis* configuration. Both the complexes are non-electrolytes in DMF and have a coordination number of six. It may therefore be assumed that the two chlorine atoms occupy the remaining *trans* positions of the octahedron as shown below:

Though the complex 3 with base III has been prepared by a different method it has the same composition as that reported by Macarovici *et al.*<sup>4</sup>. On steric grounds and in view of previous observations<sup>14,15,16</sup> one can assign the dimeric structure to this complex. The dimeric nature of the complex could not be substantiated by the molecular weight determination as this complex is not soluble in common organic solvents.

The bases IV to V can be compared with the Schiff bases formed by condensing salicylaldehyde with diamino diethyl sulphide and diaminodiethyl amine<sup>17</sup>. These bases (IV and V) are bulkier due to the *p*-substituted phenyl groups and involve comparatively much strain. The construction of the models shows that the dimeric structure involves comparatively less strain than the monomeric structure. However, the coordination number of zirconium in these complexes remains six as neither NH of the base IV nor S of the base V takes part in the coordinate bond formation. It has been observed by Bailar and Sarma<sup>18</sup> that coordination of the NH group increases the multiplicity of it and splits the band due to NH. The non-splitting of the NH band at 3300 cm<sup>-1</sup> in the complex 4 indicates that -NH- of the base IV has not taken part in coordinate bond formation. In analogy with the base IV it can be said that -S- of the base V cannot take part in the coordination. Analogous observations have also been reported by Taylor and Coleman<sup>16</sup>. All these observations show that the bases IV and V show tetradentate behaviour.

## NATIONAL CONFERENCE ON CRYSTALLOGRAPHY

A NATIONAL Conference on Crystallography, sponsored by the National Committee for Crystallography (Indian National Science Academy) was held at the Indian Institute of Science, Bangalore, from 26 to 29 December, 1974. A special Symposium on the "Structure and Conformation of Biological Molecules" and a Workshop on Crystallography were also arranged along with the Conference with financial support from the Council of Scientific and Industrial Research and the University Grants Commission respectively. The Conference, along with the Symposium and the Workshop, was organized and conducted by a Local Organizing Committee headed by Professor G. N. Ramachandran and consisting of senior crystallographers from the Indian Institute of Science, the National Aeronautical Laboratory and the Raman Research Institute.

The Conference was attended by about 130 crystallographers from different parts of India. In addition, three distinguished scientists from abroad, namely, Professor Alexander Rich of the Massachusetts Institute of Technology, Professor Walter Kauzmann of the Princeton University and Professor Henry Sobell of the Rochester University, also participated in the Conference.

The Conference, the Symposium and the Workshop were inaugurated by Professor Alexander Rich on the 26th at a function presided over by Professor S. Bhagavantam. In his inaugural address, Professor Rich described his celebrated work on the three-dimensional structure of yeast phenylalanine transfer RNA. He described the crystallographic techniques employed in the analysis and explained the three-dimensional architecture of the transfer RNA molecule.

### The Conference on Crystallography

The academic programme of the Conference (exclusive of the Symposium) consisted of four

invited talks and the presentation of about a hundred contributed papers. In his invited talk on crystal growth, Professor A. R. Patel described the reacted flux and gel methods of crystal growth developed in his laboratory at Anand. Dr. R. Chidambaram, in his talk, reviewed the evolution of single crystal diffractometers over the last decade and explained the salient features of the computer controlled diffractometer now being developed in the Bhabha Atomic Research Centre. Dr. P. Rama Rao presented a review of defects in metallic structures and their importance in understanding the strength and behaviour of metals and alloys. Dr. H. Manohar in his talk discussed the structural basis of topotactic reactions in crystals and described some examples of diffraction studies in this area. The contributed papers dealt with theoretical crystallography, the methods of structure determination, the x-ray analysis of organic and inorganic compounds, crystal defects and crystal growth, instrumentation, phase transitions and computer programming.

### The Symposium on the Structure and Conformation of Biological Molecules

The highlight of the Symposium on the "Structure and Conformation of Biological Molecules" was a talk by Professor H. M. Sobell on the x-ray visualization of drug-nucleic acid interactions. Professor Sobell demonstrated with the aid of molecular models and packing diagrams how plausible models for DNA-actinomycin and DNA-ethidium bromide interactions could be proposed on the basis of the x-ray structure analysis of model compounds. In another invited talk, Professor V. Sasisekharan discussed the importance of the effect of furanose ring puckering on the conformation of nucleic acid chains on the basis of energy calculations carried out by his group. The talk of Dr. Girish Govil was concerned with the organization of phospho-

lipids in biomembranes. The contributed papers submitted to the Symposium dealt with single crystal x-ray structure analysis of biologically important molecules, theoretical studies on the conformation of biomolecules, conformational studies in solution and enzyme crystallization.

#### The Workshop on Crystallography

The programme of the Workshop on Crystallography, held along with the Conference, consisted mainly of two evening lectures, and a one-day session of lectures and discussions on December 29. In his evening lecture on "Some problems in our understanding of protein structure", Professor W. Kauzmann showed how the information obtained from protein crystallography could be used in the study of the physical chemistry of proteins. Professor Sobell gave the other evening talk entitled "The stereochemistry of DNA strand equivalence in genetic recombination and its implication for models of recombination". The programme on

December 29 included two lecture-and-discussion sessions, one on computational problems in crystallography and the other on the direct methods in crystallography, which were led by Dr. A. Sequeira and Dr. K. Venkatesan respectively. Dr. S. Ramaseshan, in his talk on "Anomalous scattering of x-rays, neutrons and electrons", discussed the new developments in this area and reported the highlights of the recent International Conference on Anomalous Scattering held at Madrid. The other talks in the Workshop consisted of one by Dr. M. Vijayan on "Macromolecular crystallography" and another by Dr. C. Ramakrishnan on "X-ray diffraction by helical structures". In addition, the programme of the Workshop included a discussion on the x-ray diffraction equipments available in India. Representatives of some Indian manufacturers of x-ray equipments also participated in this discussion.

## LETTERS TO THE EDITOR

CRYSTAL STRUCTURE OF LEAD ACETATE  
TRIHYDRATE

CRYSTAL of lead acetate trihydrate, commonly known as sugar of lead, are obtained by the gradual evaporation of a saturated solution of the substance. The morphological characteristics of the crystals agree well with those given by Gröth<sup>1</sup>. The crystals are monoclinic with the following cell dimensions:  $a = 15.8$ ,  $b = 7.31$ ,  $c = 9.07$  Å,  $\beta = 109.8^\circ$ . The density of the substance was measured using flotation technique with a liquid mixture of bromoform and carbon tetrachloride. There are four molecules in the unit cell. Systematic absences indicate that the space group can be either  $C2$ ,  $Cm$  or  $C2/m$ .

Crystal samples used in X-ray studies were coated with collodion to prevent loss of water of hydration. There is also pronounced radiation damage on exposure to X-rays necessitating the use of different specimens for different layers in the collection of the intensity data. Three-dimensional intensity data ( $hkl$ ,  $K = 0$  to 6,  $hkl$ ,  $L = 0$  to 2) were collected using  $Cu K\alpha$  radiation by the multiple film equi-inclination technique. Spot-shape, Lorentz-polarization and absorption corrections were applied in the usual way. Using the projection data, Patterson syntheses were computed and the heavy atom, lead, was located at  $(.33, 0, .09)$ . A three-dimensional Fourier and difference-Fourier syntheses based on the phases of lead atom revealed the light atoms unambiguously. With anisotropic thermal parameters for lead and isotropic thermal parameters for the rest of the atoms, least-squares refinement was carried out using the LALS program on the IBM 370/155 computer at the Indian Institute of Technology, Madras. For 796 observed reflections, the residual index at present is 0.13 in the space group  $C2/m$  whereas 0.21 with the heavy atom alone. The crystal data and the atomic coordinates are presented in Table I.

Preliminary dielectric measurements made on powder specimens indicate that the crystal can possibly be ferroelectric upto its melting point of  $75^\circ C$ . The reported piezoelectricity<sup>2</sup> and pyroelectricity<sup>3</sup> in literature are, perhaps, attributable to this crystal. In recent EPR studies<sup>4</sup> also, it is mentioned, without stating the reason that the noncentric space group  $C2$  is favoured. But the departure from the present structure based on the centric space group will be very slight.

TABLE I

*Crystal data and fractional atomic coordinates for lead acetate trihydrate*

$$a = 15.8 \text{ Å}, \quad b = 7.31 \text{ Å}, \quad c = 9.07 \text{ Å}, \quad \beta = 109.8^\circ, \\ V = 985.7 \text{ Å}^3, \quad \rho_{\text{obs}} = 2.55 \text{ gm. cm}^{-3}, \\ \rho_{\text{calc}} = 2.554 \text{ gm. cm}^{-3}, \quad \text{F.W.} = 379.5 \text{ gm}, \quad Z = 4, \\ \mu (\lambda = 1.5418 \text{ Å}) = 346.6 \text{ cm}^{-1}.$$

| Atom  | x      | y     | z      |
|-------|--------|-------|--------|
| Pb    | 0.3314 | 0.000 | 0.0867 |
| O (1) | 0.232  | 0.000 | 0.226  |
| O (2) | 0.358  | 0.000 | 0.408  |
| O (3) | 0.265  | 0.373 | 0.099  |
| O (4) | 0.068  | 0.000 | 0.116  |
| O (5) | 0.098  | 0.500 | 0.097  |
| O (6) | 0.026  | 0.500 | 0.287  |
| C (1) | 0.277  | 0.000 | 0.369  |
| C (2) | 0.229  | 0.000 | 0.489  |
| C (3) | 0.317  | 0.500 | 0.162  |
| C (4) | 0.411  | 0.500 | 0.277  |

The first three oxygen atoms belong to the acetate groups and the latter three belong to the water molecules.

The lead atom is coordinated to eight oxygen atoms (the Pb-O distances varying from 2.31 to 3.10 Å) out of which two belong to the water molecules. It is interesting to note that both the oxygen atoms of the acetate groups coordinate with the lead. The geometry of the acetate groups resembles that found in similar structures. All the water molecules and acetate oxygens take part in a complicated network of hydrogen bonding. A noticeable feature of this hydrogen bonding is that the bonds are perpendicular to the  $b$ -axis.

Further refinement is under progress. Efforts will be made to refine the structure in the noncentric space group  $C2$  also.

The authors are thankful to Prof. K. S. Chandrasekaran for his keen interest in this problem and one of them (R. K. R) is thankful to the Council

of Scientific and Industrial Research, India, for the award of Junior Research Fellowship.

### DEUTERIUM EFFECT ON LIFETIME OF URANYL COMPLEXES IN SOLUTIONS

In solutions, uranyl ion ( $\text{UO}_2^{++}$ ) forms different complexes, viz.,  $\text{UO}_2^{++} (6\text{H}_2\text{O})$ , anionic complexes, e.g.,  $\text{UO}_2(\text{NO}_3)_2$  or  $\text{UO}_2\text{SO}_4$  and hydrolysed species  $\text{UO}_2(\text{UO}_3)_n$ , etc.<sup>1</sup> In the present study we have measured lifetimes of different uranyl complexes in various protonated solutions and their deuterated counterparts at 80° K. Deuteration has been accomplished in such a manner that for both the protonated and deuterated solutions, the conditions of pH, concentration and strength of the solvent were same except for the replacement H atoms of the solvent by D. Lifetimes of these solutions (Uranyl ion

concentration 0.1 M) obtained by exciting them at 3650 Å with the help of a pulse halfwidth 5 nsec, are given in Table I.

It is seen from Table I that nearly in all uranyl solutions, the lifetimes increase in deuterated solvents; but large deuteration effect is observed for  $\text{UO}_2^{++} (6\text{H}_2\text{O})$  complex, present in aqueous solutions of uranyl nitrate and perchlorate  $\tau_D/\tau_H \sim 6$ , whereas, no prominent increase is observed in solutions containing uranyl complexes like  $\text{UO}_2(\text{NO}_3)_2$ , etc., or in hydrolysed complexes  $\text{UO}_2(\text{NO}_3)_n$   $\tau_D/\tau_H \sim 1.2$ .

The effect of solvent deuteration, upon lifetimes, comes from inhibition of radiationless transitions which occur due to the exchange of electronic energy from the emitting state to the high frequency O-H vibrations. The overlap integral, determining the rate of radiationless transitions, becomes smaller for relatively lower frequency O-D vibrations resulting in an increase in the observed lifetime<sup>2-4</sup>. Large deuteration effect is expected to occur in the systems for which the rate for radiationless transitions is comparable with the radiative transition rate. Our results for uranyl complexes show that for  $\text{UO}_2^{++} (6\text{H}_2\text{O})$  complex, the non-radiative transitions are more pronounced in comparison to other uranyl complexes. Complexation as well as hydrolysis reduces the radiationless transition probability. Little effect of deuteration in acidic solutions suggests that for the anionic complexes, the lifetimes are closer to their radiative lifetimes. This is evident as the quantum

TABLE I

| Uranyl Solutions prot./deut.  | Complex*  | $\tau_H$ $\mu$ sec. | $\tau_D$ $\mu$ sec. | $\tau_D/\tau_H$ |

\* The complexes are in protonated solvents, in deuterated solvents H is replaced by D except for the ligand  $\text{CH}_3\text{COO}^-$ .

yield of uranyl sulphate in sulphuric acid is unity at 77°K.

The higher rate of non-radiative processes, in aqueous solutions of uranyl nitrate and perchlorate appears to be due to the presence of water molecules in the first coordination sphere of uranyl ion. In this case direct coupling between uranyl ion and water molecules facilitates non-radiative energy migration from excited uranyl ion to high frequency O-H vibrations. In acidic solutions, in the complexes like  $\text{UO}_2(\text{NO}_3)_2$  and  $\text{UO}_2\text{SO}_4$ , anions replace coordinated water molecules. Such shielding effect reduces the non-radiative dissipation of energy. The hydrolysed complexes are also shielded by coordination with  $\text{UO}_3$  and the results are similar to the anionic complexation. In the aqueous solutions of uranyl sulphate and acetate, uranyl ion is partially complexed and partially exposed to coordinate with water molecules, thereby showing somewhat greater deuteration effect than the complexed species.

## COBALT (III) HETEROCHELATES CONTAINING NONPLANAR QUADRIDENTATE LIGANDS

COBALT (III) complexes containing nonplanar quadridentate Schiff base salen [where salen  $\text{H}_2 = \text{N}, \text{N}'$ -ethylenediaminebis (salicylideneimine)] and  $\beta$ -diketones have been the object of much work<sup>1-4</sup>. In this preliminary communication we describe the synthesis of several new cobalt (III) heterochelates containing quadridentate ligands saltn or salpn [where saltn  $\text{H}_2 = \text{N}, \text{N}'$ -trimethylenediaminebis (salicylideneimine), salpn  $\text{H}_2 = \text{N}, \text{N}'$ -propylenediaminebis (salicylideneimine)] and bidentate monobasic ligands like acetylacetone, 8-hydroxyquinoline, tropolone and acetoacetanilide.

$\text{Co}(\text{saltn})$  and  $\text{Co}(\text{salpn})$  were prepared according to the method of Bailes and Calvin<sup>5</sup>.

For the preparation of the mixed ligand complexes equimolar amounts  $\text{Co}(\text{saltn})$  or  $\text{Co}(\text{salpn})$  and the appropriate bidentate ligand in absolute alcohol were refluxed and filtered. The evaporation of the filtrate produced green precipitates of the complexes. The complexes were recrystallised from ethanol or 1:1 mixture of ethanol and chloroform. The acetoacetanilide complexes were recrystallised from acetone. The characterisation data of the complexes are presented in Table I.

The electrolytic conductance measurements of the complexes in methanol indicate non-electrolytic nature of the complexes. The complexes are diamagnetic as expected for  $d^6$  cobalt (III) complexes of octahedral symmetry. The electronic spectra of the complexes in chloroform exhibit two bands at around 16500 and 25000  $\text{cm}^{-1}$  characteristic of octahedral cobalt (III) complexes<sup>6</sup>. The first band at 16500  $\text{cm}^{-1}$  is assigned to the  ${}^1\text{A}_{1g} \rightarrow {}^1\text{T}_{1g}$  transition and the second band at 2500  $\text{cm}^{-1}$  is assigned to the metal ligand transitions coupled with the

#### KINETICS OF REACTIONS OF TERTIARY AMINES WITH BENZYL HALIDES

Brown and Eldred<sup>1</sup> and Brown and Fried<sup>2</sup> have investigated quaternisation of a number of tertiary amines with alkyl halides. Baker and Nathan<sup>3</sup> have compared the reactions of pyridine and  $\alpha$ -picoline

with arylbromide and alkylbromides and the differences in reactivities have been attributed to differences in energy of activation. Solvent influences on certain quaternisation processes have also been studied by Padmanabhan and Anantakrishnan<sup>4</sup>. This note deals with the kinetics of reactions of pyridines, quinoline, isoquinoline and their derivatives with benzyl and substituted benzyl chlorides in nitrobenzene and nitrobenzene-ethanol mixture and the kinetic data have been used to compute the nucleophilicity parameters of the bases for the first time.

Kinetics has been followed by Volhard's method using A.R. grade substances mostly, except a few compounds which were purified using standard procedures.

The second order rate constants for the reactions of tertiary bases with benzyl halides have been calculated using the usual rate expression except in a few cases in nitrobenzene medium, where equilibrium was attained and in such cases the rate constant was evaluated using the modified rate expressions<sup>5</sup>.

As seen from Table I, plots of  $\log k$  for pyridines VS  $\text{Pka}$  are fairly linear except with  $\alpha$ -picoline. The order of reactivity is  $\gamma$ -picoline  $>$   $\beta$ -picoline  $>$  pyridine  $>$   $\alpha$ -picoline. Plots of  $\log k$  of bicyclic bases VS  $\text{Pka}$  shows considerable scatter probably due to want of accurate  $\text{Pka}$  values in the solvent system studied. Among the bicyclic bases, isoquinoline reacts faster than quinoline but the order is reversed when quinoline nucleus is substituted with a methyl group.

Among the benzyl chlorides, *p*-methyl benzyl chloride reacts fastest due to the electron releasing nature of the methyl substituent. The lower reactivity of chlorobenzyl chlorides can be attributed to the electron attracting nature of the substituents.

The reactions in nitrobenzene alcohol (80 : 20 V/V) are uniformly faster than in nitrobenzene. The higher reactivity in the mixed solvent is due to the protic character of the solvent.

|   | P-Cl              |           | ..            | -0.28                             |
|   | O-Cl              |           | -0.10         | -0.25                             |

TABLE III

Nucleophilic reactivity constants of tertiary bases

$\alpha$  (For Benzyl chloride) = 3.53,

$\beta$  (for Benzyl chloride) = -0.128

Substrate : Benzyl chloride Temperature :  $80^\circ \text{C}$   
 Solvent : Nitrobenzene

| Base               | H    | Nucleophilicity | $E_n$          |
|--------------------|------|-----------------|----------------|
| Pyridine           | 6.91 | 4.80<br>(4.80)  | 1.44<br>(1.44) |
| $\alpha$ -Picoline | 7.71 | 3.94<br>(3.90)  | 1.25<br>(1.24) |
| $\beta$ -Picoline  | 7.42 | 5.04<br>(5.11)  | 1.51<br>(1.53) |
| $\gamma$ -Picoline | 7.76 | 5.33<br>(5.16)  | 1.59<br>(1.55) |
| Quinoline          | 6.59 | 3.72<br>(3.55)  | 1.16<br>(1.11) |
| Isoquinoline       | 6.88 | 4.88<br>(4.96)  | 1.45<br>(1.47) |
| 2-Methyl quinoline | 7.16 | 3.96            | 1.24           |
| 3-Methyl quinoline | 7.38 | 4.02            | 1.26           |

Values in parentheses are in nitrobenzene-alcohol (80:20 V/V).

*Application of linear free energy relationship.*—Swain-Scott<sup>7</sup> and Edwards<sup>8</sup> equations have been applied to the kinetic data and parameters like nucleophilicity and  $E_a$  values for the bases used have been computed in nitrobenzene and nitrobenzene-alcohol mixtures which help in understanding the mechanism of the process to some extent<sup>9</sup>. The parameters are given in Table III.

The parameters are identical in nitrobenzene and nitrobenzene-alcohol mixture demonstrating the operation of identical mechanism in both the solvent systems.

Our thanks are due to Prof. P. S. Radhakrishnamurti, Professor of Chemistry, Berhampur University, for his keen interest and valuable suggestions.

# PHYSICO-CHEMICAL STUDIES OF SOME BIVALENT METAL ION CHELATES OF N-ACETYLACETONE ORTHANILIC ACID

THE results of physico-chemical studies on the chelates of N-Acetylacetone orthanilic acid ( $H_2AO$ ) with some bivalent metal ions are reported in this note.

Orthanilic acid supplied by SCHUCHAROT MUNCHEN was used. All other compounds were of BDH grade. The molecular weights, elemental analysis, magnetic susceptibility and electronic absorption spectra were determined by standard methods as reported earlier<sup>1</sup>.

*Preparation of  $H_2AO$  and its metal chelates.*— $H_2AO$  Schiff base was prepared by the method of Pfeiffer *et al.*<sup>2</sup>. The metal chelates were synthesised by the method of Yamada *et al.*<sup>3,4</sup> and their pyridine solvates by the method reported earlier<sup>1</sup>.

Analysis: Found C, 51.81; H, 4.99; N, 5.47; S, 12.41. Calcd. for  $C_{11}H_{13}NSO_4$ , C, 51.96; H, 5.11; N, 5.51; S, 12.59%, m.p. 160°.

*Results and Discussions.*—Elemental analysis, molecular weight and magnetic data of the hydrated chelates are given in Table I.

The molecular weight data indicate that Fe (II), Co (II), Ni (II) and Cu (II) chelates possess the composition  $[MLX_3]$  where M represents the metal ion,  $X = H_2O$  or Py and  $LH_2 = [C_{11}H_{13}NSO_4]$ . The magnetic moment values reveal the presence of 4, 3, 2 and 1 unpaired electrons in the Fe (II), Co (II), Ni (II) and Cu (II) chelates respectively. The high magnetic moment of Co (II) chelate appears to be due to spin-orbit coupling.

The electronic absorption spectra of these chelates were studied both in dioxane and pyridine solu-

TABLE I

Elemental analyses, molecular weights and magnetic moments of the metal chelates of N-acetylacetone-orthanilic acid

| Metal chelate                               | Mol. wt.    | Metal %       | N %         | H <sub>2</sub> O % | $\mu_{eff}$ (B.M.)<br>at 298° K |

Calculated values are given in parentheses. X refers to H<sub>2</sub>O. Zn (II), Pd (II), Cd (II), UO<sub>2</sub> (II) chelates were found to be diamagnetic, as expected.

ions. The frequencies and the corresponding transitions observed are summarized below.

| Complex | Observed $\nu_{\text{max}}$ (cm <sup>-1</sup> )<br>Dioxane-Pyridine | Possible transitions   |
|---------|---|--|
| Fe(II)  | 1169, 1160  | $T_{2g} \rightarrow E_g$   |
| Co(II)  | 1590, 1170<br>1170, 1160  | $T_{2g}(F) \rightarrow T_{2g}(F)$<br>$T_{2g}(F) \rightarrow A_{1g}(F)$                 |
| Ni(II)  | 1470, 1370<br>1150, 1140  | $T_{2g} \rightarrow T_{2g}(F)$<br>$A_{1g} \rightarrow T_{2g}(P)$                       |
| Cu(II)  | 1470, 1350  | $E \rightarrow T_{2g}$   |
| Pd(II)  | 1110, 1100<br>1070, 1100<br>1150, 1120                              | $A_{1g} \rightarrow B_{1g}$<br>$A_{1g} \rightarrow E_g$<br>$A_{1g} \rightarrow A_{2g}$ |

An I.R. study of  $H_2AO$  has shown three bands at 1169 cm<sup>-1</sup>, 1170 cm<sup>-1</sup> and 1150 cm<sup>-1</sup> which can be assigned to the presence of sulphonic acid ( $SO_3H$ ),  $C=N$  and enolic  $-OH$  respectively. In all the metal chelates under investigation the bands at 1169 cm<sup>-1</sup> and 1150 cm<sup>-1</sup> could not be located which suggests their elimination due to complexation.

The presence of chelated water molecules in these compounds has been confirmed by their I.R. spectra in the region 3.1-4.0  $\mu$ .

These data supported by their magnetic moments confirm an octahedral structure for  $Fe(II)$ ,  $Co(II)$ ,  $Ni(II)$  and  $Cu(II)$  chelates.

The  $Zn(II)$ ,  $Pd(II)$ ,  $Cd(II)$  and  $UO_2(II)$  also form 1 : 1 chelates and their composition can be expressed by the formula  $[MLN]$ , where M denotes the metal ion,  $LH_2 = [C_5H_5NSO_3]$  and  $N = H_2O$  or  $Py$ . The hydrated chelates and their pyridine solvates have been found to be diamagnetic. These results can be explained by assigning a tetrahedral structure for  $Zn(II)$  and  $Cd(II)$  chelates and an octahedral structure for  $UO_2(II)$  chelate. The diamagnetic behaviour of the  $Pd(II)$  chelate indicates a square-planar stereochemistry around the central  $Pd(II)$  ion. These results are also in agreement with an earlier finding<sup>1</sup>.

# SR ISOTOPE RATIOS OF THE ALBERT BASALT-IMPLICATIONS IN THE PETROGENESIS OF THE FOCAL PEAK SHIELD VOLCANO, SOUTHEAST QUEENSLAND, AUSTRALIA

IN southeast Queensland and northeast New South Wales, Australia, an extinct shield volcano, named the Focal Peak Shield Volcano, exists<sup>1</sup>. The volcanics and associated intrusives of this shield volcano are late Oligocene in age. Extrusives include, on its eastern side, the alkaline Albert Basalt and the metaluminous Mt. Gillies Rhyolite. The petrogenetic relationship between these two formations will be examined here in the light of available Sr isotope ratios. Most of the extrusives of the Albert Basalt are hawaiites, using the classification system proposed by Coombs and Wilkinson<sup>2</sup> assuming a 1-50%  $Fe_2O_3$  content<sup>3</sup>. A few basanites, alkali olivine basalts, mugearites and even a brecciated trachyte exist.

Only limited Sr isotopic information is available for the Albert Basalt (Table I).  $Sr^{87/86}$  ratios for the formation are comparable to those of continental alkali basalts and slightly higher than those normally expected for oceanic alkali basalts<sup>4</sup>. These data suggest that either the Albert Basalt was :

- (1) derived from mantle material with a high  $Sr^{87/86}$  ratio, or
- (2) contaminated by the addition of silic material, or
- (3) contaminated by selective diffusion of certain elements, including Sr, from continental crust into the basaltic magmas, or
- (4) selective migration of radiogenic Sr from crustal rocks into the magmas.

Major and trace element geochemistry discounts the possibility of contamination of the basaltic magmas by the addition of silic material alone being the major causative factor. It appears that factors (3) and (4) above are the most likely causes. Isotopic contamination would probably result not only during the active transportation of the basaltic magmas to the earth's surface, but also, to a very important degree, during temporary halts of transportation within both the mantle (if isotopically heterogeneous) and, more importantly, within the continental crust. It is considered, from field and detailed geochemical studies, that the Mt. Gillies Rhyolite was derived from the Albert Basalt which includes both undersaturated and saturated representatives. Sufficient time is required to pass for the processes of strong fractionation to generate rhyolitic differentiates from basaltic parents. Consequently, the concept of halts in the transportation of magmas is important in petrogenetic discussions. In addition, it should

3. Yamada, S., *Coordin. Chem. Reviews*, 1966, 1, 415.
4. Yamada, S., Kuse, Y. and Yamanouchi, K., *Bull. Chem. Soc.*, 1967, 40, 1864.

be noted that the plagioclase-clinopyroxene-olivine thermal barrier, often separating the fields of saturated and undersaturated basalts, appears not to have prevented siliceous differentiates being derived from the more undersaturated representatives of the Albert Basalt. This is probably due to some of the formation's basaltic magmas passing from the undersaturated to saturated field at  $P \geq 20 \text{ kb.}^2$  (i.e., at a depth approximately  $\leq 65 \text{ km}$ ) where the thermal barrier is inoperative.

In summary then Sr isotopic evidence has been useful in studies of the petrogenetic history of the Focal Peak Shield Volcano in which the Mt. Gillies Rhyolite is believed to be a strongly fractionated differentiate of the alkaline Albert Basalt. Halts in transportation of the differentiating magmas towards the earth's surface is believed to be of great importance in the petrogenesis of the rhyolitic formation.

# ON THE SIGNIFICANCE OF ENHANCED GLUTAMINE SYNTHETASE AND ITS REGULATION DURING AESTIVATION IN *PILA GLOBOSA*

In aestivating *Pila globosa* the protein content decreases and the general amino acid pool increases of which certain amino acids alone predominate<sup>1</sup>. Uric acid level increases<sup>2,3</sup> while urea content decreases<sup>4</sup> in all the tissues during aestivation indicating that the protein nitrogen is probably metabolized to uric acid during aestivation. However there are no reports on the activity levels of the enzymes concerned with the synthesis of uric acid during aestivation. The present report concerns the distribution and the activity of glutamine synthetase during aestivation, since this enzyme level determines the glutamine level which is known to contribute to N-3 and N-9 of the uric acid molecule.

Glutamine synthetase activity in the hepatopancreas, mantle and foot of the active and three months aestivated *Pila globosa* was estimated by the method of Iqbal and Wu<sup>4</sup>.

It was observed that the synthesis of glutamine from glutamic acid is limited to hepatopancreas since the other two tissues, namely, mantle and foot had no detectable activity of the enzyme. Thus in mantle and foot the rate of glutamine synthesis is slowest thereby limiting uric acid biosynthesis. Such control mechanisms limiting the entire pathway by some slow steps in reaction sequences are not uncommon in animal biochemistry. The low level of this enzyme will be responsible for lower glutamate metabolism into glutamine thus resulting in accumulation of glutamate<sup>1,5</sup> reported during aestivating *Pila globosa*.

There is a 100% increase in the glutamine synthetase in hepatopancreas of the 30 days aestivating *Pila globosa* and the activity is maintained at that level even in 3 months aestivating snails. In active snails the ammonia produced in the metabolism is constantly excreted thereby averting the possible ammonia toxicity to the tissue metabolism. In the absence of such ammonia toxicity the  $\alpha$ -ketoglutarate could have been metabolized without the necessity of being converted to glutamate. In the present investigation the aestivating snail, since the possibility of excretion is less, there is every danger of accumulation of ammonia to the level of lethality. To prevent this catastrophe the aestivating metabolism is geared to alternate stepping up of processes that knock out ammonia which could be as follows.

$\alpha$ -Ketoglutarate dehydrogenase complex was shown to be inhibited by  $\text{NADH}_2$ <sup>13</sup>. The increased cytoplasmic and mitochondrial  $\text{NADH}_2/\text{NAD}$  ratio have been reported in the liver of turtle and rat

TABLE I

Glutamine synthetase activity in tissues of active and different periods of aestivated *Pila globosa*

| Sl. No. | Tissues        | Active     | 1 Month aestivated                    | 2 Months aestivated                 | 3 Months aestivated                    |

## Note:

1. — : indicates activity below the level of detection.
2. — : indicates standard deviation (S.D.).
3. —% : indicates percent over active.
4.  $p$ — : level of significance.

during hypoxia<sup>14,15</sup>. Moreover, succinate dehydrogenase activity was reported to decrease in aestivation<sup>11,12</sup> indicating that the formation of succinate through  $\alpha$ -ketoglutarate dehydrogenase complex is less. Under these conditions it is likely that the amination of the  $\alpha$ -ketoglutarate by glutamate dehydrogenase is preferred to oxidation by  $\alpha$ -ketoglutarate dehydrogenase. Increased glutamate dehydrogenase reported during aestivation<sup>16</sup> is consistent with the above inference. Glutamic acid is shown to be a potent inhibitor of the nervous system<sup>17</sup> and many enzyme systems in *Pila globosa*. Hence it is converted to less toxic glutamine.

The activity pattern of glutamine synthetase is modulated by adenylation of the enzyme by ATP. This process is catalyzed by adenylyl transferase. The increase in the level of glutamine and ATP activate this enzyme which results in the elevated levels of glutamine synthetase-AMP complexes<sup>7</sup>. The adenylation complex has low activity and consequently the formation of further glutamine is reduced<sup>8,9</sup>. Glutamine synthetase — 12 ATP

In the aestivated animal tissues ATP and glutamine levels were high<sup>10</sup> which under normal conditions activate adenylyl transferase, resulting in a decrease of glutamine synthetase activity. On the contrary, an increase in the activity of glutamine synthetase is observed in aestivated animal tissues indicating nonadenylation of the enzyme possibly by the stopped up deadenylation.  $\alpha$ -Ketoglutarate and ammonia are known to activate deadenylylating systems<sup>6</sup>. This peculiar shift is probably for meeting the emergency survival demand against ammonia toxicity.

Thus in the aestivating *Pila globosa* though the conditions are favourable for adenylation of

glutamine synthetase as a consequence of high levels of ATP and glutamine adenylyl transferase is not active. Hence there is a shift in the pattern of enzyme regulation towards the activation of deadenylylating enzyme or insensitization of adenylylating system.

# CHEMICALLY INDUCED SPERM GRANULOMA IN RAT

RECENTLY Cooper and Jackson<sup>1</sup> reported that ethylenedimethane sulphonate (EDS), an alkylating agent, caused sperm retention cysts in the rat epididymis.  $\alpha$ -chlorohydrin an active alkylating chemical possessing the specific biological property of "functionally" inactivating epididymal sperm frequently induces pathological changes in the epididymis.

The present investigation is concerned to study the pathological changes involved in the  $\alpha$ -chlorohydrin induced sperm retention cysts/or granuloma in rat and to discuss the biologic significance of the phenomena observed.

$\alpha$ -chlorohydrin (3-chloro-1, 2-propanediol) (sp. gr. 1.326) was supplied by the Upjohn Company, Kalamazoo, Michigan, in 0.25% aqueous (1.3 g/ml) methyl cellulose. A working solution was made by diluting the stock solution with distilled water. Ten adult male Wistar rats from the randomly mated colony were given  $\alpha$ -chlorohydrin orally (25 mg/kg/day for 24 days). The controls received distilled water only. The animals were given rat food (Purina chow: Hindustan Lever Private Ltd.), wet gram and water *ad libitum*.

Twenty-four hours after the administration of the final dose of  $\alpha$ -chlorohydrin, the rats were killed by rapid decapitation. Final body weight, and the weights of testis, epididymis, seminal vesicle, ventral prostate and levator ani muscles were recorded. The epididymis were examined with naked eye for cysts formations.

Grossly sperm retention cysts were evident as yellow nodular masses varying in size from 1.25 mm to 3.5 mm in the greatest dimension. The most frequent site was the lower pole of the epididymis.

In histologic preparations, the cyst consisted of a central pool of sperm surrounded by macrophages and histocytes (Fig. 1). The epididymis contained

mononuclear cells, spermatocytes and multinucleated spermatid elements. Distension of the coils of ductus-epididymis and atrophy of the lining-epithelium were conspicuous. Fibrosis and hyalinization of the epididymal tubules were common.

FIG. 1. Showing the sperm retention cyst in the cauda epididymis of rat after  $\alpha$ -chlorohydrin treatment (Total dose 24 mg). Note the central pool of sperms surrounded by macrophages (—)  $\times 24$  HE.

The present investigation points out the possible cause for chemically induced spermatid granuloma formation is, the damage to the epididymal epithelium for the leakage of sperm. The sperm may then become involved with the inflammatory process in the stroma, resulting in the formation of the sperm granuloma. From a practical point of view, spermatid granulomas are important because they stimulate other lesions, particularly tuberculous epididymitis<sup>2</sup>.

In the rat, the epididymis is androgen dependent.  $\alpha$ -chlorohydrin produces marked inhibition of the accessory sexual structures (seminal vesicle, ventral prostate and levator ani muscles; Table I) indicating pharmacological action on the androgenic

#### A NOTE ON THE COMPARATIVE STUDY OF FREE AMINO-ACIDS CONTENT BETWEEN WILD SALT TOLERANT RICE AND CULTIVATED RICE VARIETIES

Wild rice (*Oryza coarctata*) grows profusely on saline marshy area (electrical conductivity above 25 m.mhos/cm) near the institute farm. An attempt has been made to study the physiology of salt tolerance of this wild rice. This note reports free amino-acid content of wild and cultivated rice varieties.

For a comparative study along with the wild rice, a local salt-tolerant rice variety Damodar, and a high yielding rice variety Jaya was selected. Plant samples were collected from young seedlings (33 days old). Free amino-acids were analysed from fresh samples by paper chromatographic method as suggested by Plaisted<sup>1</sup>. Leaf and stem were analysed separately. Free amino-acid content of the rice varieties are given in Table I.

The results show that alanine, serine and glycine, histidine and arginine, and proline content of wild salt-tolerant rice—*Oryza coarctata*—is more as compared to cultivated rice varieties. It is interesting to note that proline content of *Oryza coarctata* is quite high compared to the other varieties. From comparative rates of proline accumulation in various plant organs Singh *et al.* (1973) postulated that a water deficit or osmotic stress induces proline accumulation in the leaves from where it is translocated to the roots and other plant organs. Stewart *et al.* (1966) suggested that proline may be the major source of energy and nitrogen during immediate post-stress metabolism. From this it can be concluded that possibly proline which accumulates under osmotic stress condition is

TABLE I

*A comparative study of free amino-acids content between wild salt-tolerant rice and cultivated rice varieties (in microgram gram of dry matter)*

| Name of the Amino-acids      | <i>Oryza coarctata</i> (wild rice) |          | Damodar  |          | Jaya     |        |

#### PRENATAL DETECTION OF FETAL SEX\*

In 1956 Fuchs and Riis showed the possibility of foetal sex determination from amniotic fluid cells using Barr body technique. In 1971 Khudr and Benirschke used fluorescence studies to locate Y-chromosome (Y-body) in the nuclei of amniotic fluid cells in male cases.

Figs. 1-2

The amniotic fluid cells are of fetal origin and derived mainly from fetal skin and amnion. The present paper deals with the use of simple and rapid techniques (Barr body and fluorescence method) available for prenatal sex determination.

**Material and Methods.**—The amniotic fluid samples were obtained from 15 patients undergoing therapeutic abortion by intrauterine prostaglandin or by saline injection between 10 to 18 weeks of gestation. One sample was obtained from a patient who had two sons and 8 other male members in

the family suffering from leukodystrophy. All abortions were done for psychiatric and health reasons.

The volume of amniotic fluid sample obtained varied from 5 ml to 12 ml depending on the month of pregnancy, and the technique used for abortion.

The sample was centrifuged at 1000 r.p.m. for 10 minutes. After discarding the supernatant, the cell pellet was resuspended and fixed in acetic acid alcohol (3 parts methanol — 1 acetic acid) for 20 minutes. The smears were prepared and some of the slides were stained in Giemsa stain for X-chromatin and the rest was stained in 0.5% quinacrine dihydrochloride (Atebrin) for fluorescence microscopy to study Y-body.

**Results and Comments.**—Results were confirmed by the gross examination of fetuses, mainly of external genitalia. The results agreed in all the cases except one, where the sample was not sufficient for the satisfactory preparation.

The amniotic fluid cells of male fetuses showed a single fluorescent body usually located peripherally sometimes eccentrically within the nucleus (Fig. 1). In case of a female, amniotic fluid cells showed typical Barr body (Fig. 2) but no such fluorescent

body. One hundred cells were scanned from each preparation and in the nuclei of male fetuses a typical fluorescent body was found in 20% to 30% of the cells and in the nuclei of female fetuses 20% to 60% of typical Barr body was found. The variation in number may be due to presence of different types of cells. In a case of leukodystrophy the amniotic fluid cells showed male fetus and the patient decided to continue pregnancy. She delivered a male child which confirmed our prediction of the sex.

This preliminary study shows that the method used may be of great help in determining the sex of the fetus at the early stage of pregnancy. It is a test which can be performed in less than one hour.

### RELATION OF SPORULATION TO FUSARIC ACID PRODUCTION IN MUSKMELON WILT PATHOGEN

FUSARIC acid (FA), a wilt toxin, is produced by many fusaria both *in vitro* and *in vivo*. From this laboratory Bhaskaran and Prasad<sup>1</sup> reported the *in vitro* production of FA by the muskmelon wilt pathogen [*Fusarium oxysporum* f. *melonis* (Leach and Currence) Snyder and Hans.]. Interestingly the toxin production was more in media which favoured good sporulation<sup>2</sup>. Studies on the relation between sporulation and fusaric acid production were made and the results are reported here.

Hundred ml aliquot of sterilized Czapek's medium in 250 ml conical flasks were inoculated with 8 mm disc of the actively growing fungus and incubated at room temperature ( $28 \pm 2^\circ \text{C}$ ). At the end of incubation period, the flasks were shaken in a rotary shaker for 30 min and the spore load was estimated by Haemoagglometer counts. The content was passed through a double layered cheese cloth, washed with distilled water. The mycelial mat was separated from cheese cloth, blotted and weighed. The filtrate was centrifuged to separate spores from culture filtrate. The fusaric acid in culture filtrate, mycelium and spores was detected following the respective methods<sup>3,4</sup>. The presence of FA was confirmed by paper chromatography. The influence of certain media, viz., Czapek's, Coon's, Horne and Mittar's and Park's suggested for *Fusarium*<sup>5</sup> was tried for assessing growth, sporulation and FA level.

The effect of incubation periods on growth, sporulation and FA production is shown in Table I and the effect of different media on growth and FA production is presented in Table II. Among the media tested, Czapek's medium favoured relatively higher sporulation and FA production. Growth

\* FA in inhibition annules (mm<sup>2</sup>).

studies in Czapek's broth indicated maximum sporulation and FA production on 20th day and growth on 30th day. Thus a parallelism existed between sporulation and FA production by this pathogen. Sandhu<sup>6</sup> demonstrated that FA is a product of active metabolism, probably ultimately connected with tricarboxylic acid cycle. The accelerated metabolism during sporulation may be the cause of more FA production. The toxin level in mycelium and conidia showed a marked variation. FA in mycelium and conidia was first reported<sup>2</sup> in *Fusarium oxysporum* f. *vasinfectum*. Toxin in mycelium and

conidia was estimated for the first time in this pathogen. Toxin content of conidia was more than that of the mycelium produced per unit quantity of medium. These results further substantiate that there is a definite positive correlation between sporulation and toxin production.

The senior author is grateful to the Indian Council of Agricultural Research for the award of a Junior Research Fellowship during the period of which the work was carried out. The supply of FA by Prof. H. Kern of Zurich, Switzerland, is gratefully acknowledged.

#### A BIOLOGICAL APPROACH TO THE CONTROL OF MAIZE BORER *CHILO ZONELLUS* (SWINHOE)

ISOLATIONS made from the body surface of the borer, *Chilo zonellus* (Swinhoe), its frass deposits and rotted maize stalk in the vicinity of borer tunnels gave the following fungi: *Cephalosporium acremonium*, *Fusarium moniliforme*, *Aspergillus* sp., *Cladosporium* sp., *Penicillium* sp., *Mucor* sp., *Rhizopus* sp., *Trichoderma* sp., *Botrytis* sp. and a *Fusarium* sp.. Among the bacterial forms were *Pseudomonas* sp., and *Bacillus* sp.

A species of *Fusarium* which was identified as *Fusarium aleyrodis* Petch was found to be pathogenic on this insect, others were not.

For confirmation of the pathogenicity of *F. aleyrodis*, originally isolated from the insect body surface, field collected larvae ranging from 2nd to 4th instar were individually immersed in fungal spore suspension. A control was maintained. The larvae were fed with finely chopped pieces of maize stem. Whitish fungal mat appeared gradually on the insect's body. Single spore isolation from this hyphal mat yielded *F. aleyrodis* Petch. Repeated patho-

genicity tests also confirmed it. The larvae during fungal colonization became sluggish, stopped feeding, turned brown and succumbed within 2-5 days of infection. Toxicity of the fungus is believed to be responsible for pathogenic action on the insect<sup>1,2,3</sup>. Mechanism of fungal action could be ascertained by observing separately the effect of fungal spore spray and its crude toxin on the insect larvae.

Spore spraying showed that by the 7th day the insects were killed (Table I). Fungal mat appeared on the 8th day and on the 9th day the entire insect body was covered with sporulating hyphae.

TABLE I

Effect of fungal spore spray on larvae of *Chilo zonellus* (20 larvae were used in each replication)

| Days | Number of larvae dead                                  |     |     |     |
|------|--|-----|-----|-----|
|      | Replications   |     |     |     |
|      | 1  | 2   | 3   | 4   |
| 1    | ..   | ..  | ..  | ..  |
| 2    | ..   | ..  | ..  | ..  |
| 3    | ..   | ..  | ..  | ..  |
| 4    | ..   | ..  | ..  | 1   |

| 6    | 8  | 8   | 9   | 7   |
| 7    | All  | All | All | All |
| 8    | Fungal mat seen on the insect                          |     |     |     |
| 9    | Fungal mat as well as spores found on all the insects. |     |     |     |

Crude toxin obtained from *F. aleyrodis* culture grown in Richard's liquid medium, when applied topically on the larvae, killed them. The toxin-treated insects stopped taking food, showed tetanic reaction and subsequently died. The larvae started dying right from the very beginning reaching the maximum on the 13th day (Table II). Mortality rate progressed with number of days of incubation.

*Chilo zonellus* has been found to be attacked and pathogenically colonized by another fungus *Beauveria densa* Link.<sup>4,5</sup>. *Chilo partellus* was effected by *Aspergillus flavus* and a *Fusarium* sp.<sup>1</sup>. The pathogenic attack of *Chilo zonellus* by *Fusarium aleyrodis* Petch, adds to the list of fungi parasitic on insects. Spraying of the insect with spore suspension or treatment with crude toxin of this fungus could be of biological control value.

TABLE II  
Effect of fungal toxin on *Chilo zonellus*

| Period of exposure to toxin (Days) | Average number of larvae dead when sprayed with toxin (20 larvae) |    |    |    |    |    |    |

# NOTE ON THE OBSERVATION OF THE FUNGUS *GONGRONELLA BUTLERI* (LINDN.) PEYRONEL AND DALVESCO IN COCONUT ROOT

WHILE examining the longitudinal sections of coconut roots in connection with the investigations on the root (wilt) disease, it was observed that the

vascular tissue of the coconut root contained sporangia-like bodies (Fig. 1). Attempts were made to culture the organism by different methods. Root tissue containing the sporangium as well as sporangia separated by mixing the root tissue in Waring blender and squeezing through cotton wool were plated on potato-dextrose agar medium containing yeast extract and thiamine. 0.1% streptomycin was added to suppress the bacterial growth.

FIG. 1. Sporangium inside the cell.  $\times 125$ .

Fluffy growth with aerial mycelium was observed and the hyphae 2.0 to 3.5  $\mu$ m in width, were aseptate. Sporangium was apical with a diameter of 4 to 16  $\mu$ m. The fungus was identified as *Gongronella butleri* (Lindn.) Peyronel and Dalvesco belonging to the family Mortierellaceae of the order Mucorales under Phycomycetes. This appears to be the first report in coconut from India and is an addition to the list of fungi occurring in South India (Rangaswamy *et al.*, 1970). Further study to find out the association of the fungus, if any, with the root (wilt) disease complex is in progress.

Thanks are due to the Director, Commonwealth Mycological Institute, Kew, England, for the identification of the fungus and to Dr. K. Radha and Dr. P. Shanta, of the Central Plantation Crops Research Institute, Regional Station, Kayangulam, for suggestions in this line of work.

# STUDIES ON GROWTH INHIBITION OF *FUSARIUM MONILIFORME* SHELDON BY SOME METALLIC CATIONS AND ANION IN CULTURE

INTEREST in the fungistatic activity of ions of heavy metals have developed from the attempts to control fungal pathogens<sup>1</sup>. Such fungistatic action has been attributed to a disruption of cellular metabolism

then incubated at 30° C in the dark. Three replicates were made for each concentration. Control sets (without the chemicals) were maintained under identical conditions. Mycelial growth at different concentrations was measured at 3, 6 and 9 days of the growth.

The differential growth has been recorded in Table I.

TABLE I

Effect of NaCN, ZnSO<sub>4</sub>, CuSO<sub>4</sub> and Co (NO<sub>3</sub>)<sub>2</sub> on the mycelial growth of *Fusarium moniliforme* Sheldon after 3, 6 and 9 days

| Concentrations of<br>the chemicals<br>(Molar) | Growth in diameter of the mycelia (cm)* |        |        |                   |        |        |                   |        |        |                                   |        |        |
|---|---|--------|--------|-------------------|--------|--------|-------------------|--------|--------|-----------------------------------|--------|--------|
|   | NaCN                                    |        |        | ZnSO <sub>4</sub> |        |        | CuSO <sub>4</sub> |        |        | CO(NO <sub>3</sub> ) <sub>2</sub> |        |        |
|   | 3 days                                  | 6 days | 9 days | 3 days            | 6 days | 9 days | 3 days            | 6 days | 9 days | 3 days                            | 6 days | 9 days |

\* Average of three replicates.

due mostly to non-specific inhibition of a wide range of enzymes and co-enzymes particularly those dependent on sulphhydryl groups. The present investigation has been designed to study the metabolic inhibition by some metallic cations and the cyanide anion as indicated by growth inhibition of *Fusarium moniliforme* Sheldon in culture with a view to suggesting an effective fungicide for controlling the organism.

The test-fungus, *Fusarium moniliforme*, was isolated from malformations of mango inflorescence collected from Burdwan, West Bengal, 1972. Different concentrations of NaCN, ZnSO<sub>4</sub>, CuSO<sub>4</sub> and Co(NO<sub>3</sub>)<sub>2</sub> were mixed with Czapek's synthetic agar media and adjusted to the optimum pH 6.4. The substances selected in the present investigation are known metabolic inhibitors for micro-organisms. The relative tolerance of the pathogen against the substance can be effectively employed in combating the disease through growth inhibition. The media were sterilized, plated and inoculated finally at the centre with mycelia from the test-fungus grown on Czapek's synthetic agar medium. The samples were

It is evident from the result that Zn, Cu, Co and cyanide ions have distinct inhibitory effect on growth of the test-fungus. Growth is completely inhibited in Cu, Co, Zn and cyanide at concentrations above 10<sup>-4</sup>, 10<sup>-3</sup>, 10<sup>-2</sup>, 10<sup>-2</sup> molar respectively revealing thereby that Cu is the most toxic one among the three metallic cations followed by Co and Zn. This is in full conformity with the previous observations. Toxic actions of cations and the anion are considered to act as inhibitors by inactivating the enzymes. All the metallic cations have, however, been found to promote growth at very low concentrations (10<sup>-7</sup>) revealing thereby their importance as micronutrients.

# A NEW GENE IN SOYBEAN [*GLYCINE MAX* (L.) MERR.] CONDITIONING HYPOCOTYL PIGMENTATION\*

JOHNSON AND BERNARD (1962) have listed all the genes identified in soybean [*Glycine max* (L.) Merr.] controlling qualitative characters till that date. No gene is, however, listed there which controls hypocotyl pigmentation in soybean and neither it is reported yet.

mented and non-pigmented parents were studied for pigmentation of hypocotyls in  $F_1$  generation and the  $F_2$  segregation pattern was recorded. Each of these five crosses, considered for the study, was treated as separate family and the  $\chi^2$  for segregation was calculated separately. The  $\chi^2$ s for deviation and heterogeneity were computed. The results of this analysis and the respective  $F_1$  characteristics are given in Table I.

TABLE I

| Crosses           | Hypocotyl<br>coloura-<br>tion of F <sub>1</sub> | F <sub>2</sub> segregation for hypocotyl colouration |        | $\chi^2$<br>(3: 1) | P<br>lies between |
|-------------------|---|--|--------|--------------------|-------------------|
|                   |   | Pigmented  | Green  |                    |                   |

|                   |   | Exp. 432   | 144    |                    |                   |
|                   |   | $\chi^2$   | d.f.   | P                  |                   |
| Deviation         |   | .4810  | 1      | .5-.3              |                   |
| Heterogeneity     |   | 1.0292   | 4      | .95-.90            |                   |

In the course of studying several crosses made with objectives other than genetical studies alone, some of the heterozygotes were found to segregate for the hypocotyl colouration. The pigmentation in soybean appears on germination and emergence of the hypocotyl above ground and persists till the plant ages. On the other hand, the non-pigmented types do not form any pigment at all on germination and neither on aging.

Of the seven parents involved in the various crosses two, viz., Lee and Amsoy produced pigmented hypocotyls while five, viz., Masterpiece, Bragg, Hill, Hardee and Telstar produced green hypocotyls. Five sets of crosses involving pig-

Considered individually, in each of the crosses a 3 pigmented : 1 green ratio fitted very well showing complete dominance of the pigmented character in  $F_1$ . The  $\chi^2$  for deviation also indicated that this ratio fitted well when all the crosses were considered together. The result of  $\chi^2$  analysis for heterogeneity indicated clearly that all the crosses fitted well to 3 : 1 ratio.

Thus the character pigmented and green hypocotyl colouration appear to be governed by a single gene. A symbolisation of  $Hy$ , is suggested for the gene conditioning pigmented character of the hypocotyl. Soybean being a difficult material for the purpose of crossing because of its having very

small sized flowers, a breeder would like to be sure of the genuineness of the crosses he takes up. This character of hypocotyl pigmentation can be advantageously utilised as a marker gene.

#### NOTE ON THE DEVELOPMENT OF VESICULAR-ARBUSCULAR MYCORRHIZA— *ENDOGONE FASCICULATA* IN COCONUT ROOT

OF the various mycorrhizas reported the most widespread is the so-called vesicular-arbuscular type (Nicolson, 1967). Gerdemann (1968) made a review on this and later more than hundred papers have been published on this aspect, reviewed by Mosse (1973). The long standing speculation about the identity of vesicular-arbuscular endophytes (Gerdemann, 1968) has largely been resolved in favour of one or another species of *Endogone*. Improvement in growth and also the uptake of

increased phosphate was observed in many plants having micorrhizal association (Mosse, 1973). Occurrence of the vesicular-arbuscular mycorrhiza was noted in the roots of healthy and diseased coconut palm while studying the lower form of fungi associated with coconut root.

Coconut root materials were collected from different places in Kerala. Longitudinal sections of these were stained by boiling for one minute in acid fuchsin-lacto-phenol, destained and mounted in clear lacto-phenol for microscopic examinations. The hyphae on the root surface were broad with globules inside, measured 12 to 16  $\mu$  in width whereas the hyphae in the inner cortical cells measured 2 to 8  $\mu$  in width. The mycelium on the surface as well as inner cells appeared swollen at the apical portion to form vesicles ranging in size from 40  $\mu$  to 100  $\mu$  (Fig. 1). Dark thick-walled vesicles were also seen on the surface of the root. This was identified as *Endogone fasciculata*. This appears to be the first report on coconut.

This fungus was also observed in the roots of *Cassia tora*, *Melothria* sp., *Phyllanthus neuri*, *Solanum nigrum*, *Leucas aspera*, *Mullugo* sp., *Physalis minima*, etc., common weeds growing in coconut gardens.

Grateful thanks are due to Dr. Harley, Professor, Forest Science, Oxford University and Dr. T. H.

#### A NEW LEAF BLIGHT OF *CLERODENDRON FRAGRANS*, R. BR.

A SEVERE leaf blight disease of *Clerodendron fragrans*, R. Br., a roadside and a popular ornamental plant, was observed during the summer season of 1973 and 1974 around Madanapalle, Chittoor District, Andhra Pradesh. The disease manifests itself in the form of irregular grey brown necrotic areas or patches measuring 4–14 mm long in size. The disease is very characteristic in that the patches appear or begin mostly along the margins and tips of the leaves. These areas gradually extend downwards along the margin involving the major part of the leaf tissue, ultimately resulting in blight (Fig. 1). In cases of severe infection, the plants

FIG. 1

look withered and could be spotted from a distance. Individual spots appear very rarely in the middle of the leaves. Severe attack results in complete drying of the leaves and occasional defoliation. The young as well as mature leaves were seen to be equally attacked.

The fungus was isolated by plating on PDA medium and all the single spore isolations made were found to be identical. The fungus was established in pure culture on PDA and its pathogenicity was proved by spraying spore suspension (prepared in sterile water from one week old culture) on the leaves of around one month old healthy plants. Slight injuries were made over some of the leaves with a sterile needle before inoculation. Control plants were sprayed with sterile water only. The inoculated plants were kept inside a humid chamber for 48 hours. Typical blight symptoms developed in 10–12 days in both the injured and uninjured leaves but none in the control. Re-isolations yielded the original fungus.

Aerial mycelium bluish green, cottony, abundant and appearing somewhat powdery with conidial formation and produced dark blue pigmentation on the medium. The hyphae septate, branched and measured 3–4.5  $\mu$  in width. On the leaf, the pathogen produced conidiophores and conidia. Conidiophores light to dark brown simple or branched having distinct geniculations. Conidia yellowish brown, obclavate, smooth walled 2–7 (3–8 celled), transverse and 1–2 longitudinal septa with or without beak. The length of the conidia varies (with beak) from 21 to 45  $\mu$  and width 3 to 15  $\mu$ .

The causal organism has been identified and confirmed as *Alternaria* state of *Pleospora infectoria* Fuckel. (IMI 184579).

Grateful thanks are due to Dr. Ellis of CMI Ferry Lane, Kew, England, for identification of the fungus and to Prof. V. S. R. Das for providing necessary facilities.

#### CYTOLOGICAL STUDY OF A POLYPLOID O RADISH OBTAINED AS A RESULT OF INBREEDING

ALMOST all the inbred lines of radish (*Raphanus sativus* L. var. *radicola* Pers.) in the genetic collection of Dr. S. I. Narbut of the Chair of Genetics and Plant Breeding, Leningrad State University, Leningrad (USSR), significantly differ in many characters from their original populations and are generally characterized by reduced fertility<sup>1</sup>. One of the lines, namely, LB-274, which was isolated

from the Russian variety "Virovsky bellie", was found to be highly uniform and homozygous with no further segregation in the 8th generation of inbreeding. In contrast to population, its plants had practically no anthocyanin pigments in the stem and leaves and the flowers were dark-violet in colour. In the year 1971, i.e., in the 15th generation of inbreeding, two of its plants appeared to differ from the rest in the size of the leaves, flowers and growth. They were not only completely self-sterile but also produced no seed at all even under panmixis. These plants were suspected to be autotetraploids. A cytological investigation was, therefore, undertaken to see whether these plants were polyploids or not.

For cytological analysis flower buds from suspected polyploid plants as well as the plants of the inbred line, LB-274, were fixed in the Carnoy's solution for six hours. The anthers were squashed in 1% acetocarmine and examined. 50 pollen mother cells were scored in each case.

The plants of the inbred line, LB-274, showed normal meiotic division, forming 9 bivalents at Metaphase-I. The number of rod bivalents, however, varied from one to three per cell. But quite a different picture was found in the plants, suspected to be tetraploids. In them all the p.m.c. were polyploids with various types of configurations known for a typical autotetraploid. No diploid cell was observed. An analysis of 50 cells at meiosis gave the following results :

| Quadri-valents | Trivalents | Bivalents | Uni-valents | No. of cells |
|----------------|------------|-----------|-------------|--------------|
| 3              | 3          | 5         | 5           | 15           |
| 2              | 5          | 4         | 5           | 12           |
| 1              | 7          | 4         | 3           | 9            |
| 0              | 6          | 5         | 8           | 6            |
| 5              | 2          | 2         | 6           | 5            |
| 2              | 4          | 3         | 10          | 3            |

Their complete sterility may be attributed to highly irregular meiosis and self-incompatibility.

Presence of polyploid cells in the inbred lines of allogamous populations is not new. It has been reported in rye<sup>2-3</sup>. Rees<sup>4</sup> has noted 1% polyploid cells in an inbred line of rye. Such cells have also been observed in one of the inbred lines of radish, LS-337/25<sup>5</sup>. From these, errors at the pre-meiotic mitoses have been inferred in the homozygotes. It seems that in the present case pre-meiotic errors have led to the formation of unreduced diploid gametes which on fusion gave rise to polyploid plants.

The author wishes to record his sincere thanks to Dr. S. I. Narbut of the Chair of Genetics and Plant Breeding, Leningrad State University, Leningrad, for the material.

### PEMPHIGUS BURSARIUS LINN. PRODUCING GALLS ON LOMBARDY POPLAR IN KASHMIR

THE Lombardy Poplar, *Populus nigra italica* Muenchh., is commonly grown in Kashmir on the roadsides and is a graceful avenue tree. The author collected a large number of pear-shaped or irregularly purse-shaped galls formed at various positions on the leaf stalks (Fig. 1). The causative agent was subsequently identified as *Pemphigus bursarius* (L.) (Homoptera : Aphididae). These galls were particularly more numerous on the lower leaves. On dissection each gall was found occupied by a large sized fundatrix, a considerable number of alate females, numerous young ones belonging to various developmental stages, honey-dew and cast skins entangled in a white powdery matter.

FIG. 1. Galls of *Pemphigus bursarius* (L.) on Lombardy Poplar. (X) Beak-like escape vent in the gall.

The gall formation gets initiated in early spring when a fundatrix hatching from an over-wintered egg pierces the petiole of an unfolding leaf to suck the sap. The plant cells at this region multiply so as to give rise to a rather lopsided purse-like structure enclosing the fundatrix. The fundatrix reproduces asexually within the gall to give rise to a generation of alate viviparous females which

escape from the gall in late summer particularly during August, when most of such galls are found empty. Populations of this aphid were detected on younger shoots of Lombardy Poplars in early autumn, and were found to consist of both males and females. It could not be ascertained in the preliminary observations whether these aphids had dispersed to the younger shoots after escaping from the mature galls, or had meanwhile migrated to the roots of various Compositae which serve as the secondary hosts for this aphid elsewhere<sup>1</sup>, before returning to the Lombardy Poplars in early autumn. The autumn generation reproduces sexually and the eggs over-winter on the young twigs. This aphid appeared to be exclusively restricted to the Lombardy Poplars and was not recovered from any other *Populus* species in Kashmir. The average sized galls measured 1.5–2.0 cm. This is the first report of *Pemphigus bursarius* (L.) from Kashmir. Govt. Agriculture College, M. ZAKA-UR-RAB. Sopore (Wadura), Kashmir, August 12, 1974.

### STUDIES IN GERANIALES

#### III. The Structure and the Development of the Fruit Wall in *Averrhoa carambola* L.

*Averrhoa carambola*, a member of the family Oxalidaceae, is a moderate sized tree, with minute rose-purple flowers, arranged in axillary cymes, often forming panicles. The fruit is a five or six angled berry with acute lobes and arillate seeds. Since these fruits are rich in acid juice, they are eaten raw, cooked or preserved, and are prescribed as antiscorbutics. The structure and the development of the fruit wall has not yet been worked out in this interesting genus.

The fruits of different ages, collected in August 1972 from plants growing locally, were preserved in 70% alcohol. The material was dehydrate by passing through tertiary butyl alcohol grades and embedded in paraffin wax. The study was based on transverse sections of the fruits of different ages, varying in length from 3 mm to 40 mm and stained in Safranin-Fast green.

In a T.S., the pericarp of a young fruit (3 mm) is 14 or 15 cells thick, the cells being compact and parenchymatous. The cells of the outer epidermis are more or less rectangular and those of the inner epidermis are tangentially elongated. The layer, lying immediately next to the inner epidermis also has cells which are somewhat tangentially elongated. The cells are richly cytoplasmic and undergo both anticlinal and periclinal divisions. At this stage a

few tannin cells are found interspersed in the pericarp (Fig. 1).

FIGS. 1–4. *Averrhoa carambola* L. Some stages in the development of fruit wall as understood from transverse sections. Fig. 1. From fruit about 3 mm in length,  $\times 260$ . Fig. 2. From fruit 6–8 mm in length,  $\times 60$ . Fig. 3. From fruit 12–15 mm in length,  $\times 20$ . Fig. 4. From fruit about 40 mm in length,  $\times 20$ .

The cell divisions continue until the fruit attains a length of about 6–8 mm. At this stage the pericarp may be distinguished into three more or less distinct zones: (i) exocarp or epicarp consisting of a few layers of small, more or less cubical cells; (ii) mesocarp that constitutes the main bulk of the pericarp with several layers of irregular cells and (iii) endocarp with elongated cells of 4 or 5 layers including the inner epidermis. The development of tannin is maximum at this stage (Fig. 2).

In a fruit measuring 12–15 mm in length cell division ceases to occur and the further growth is entirely by cell enlargement, especially in the mesocarp. Tannin also disappears by this time and the cells of the endocarp become compressed by the enlarging cells of the mesocarp (Fig. 3).

The subsequent increase in the size of the fruit is by cell enlargement in the region of the mesocarp. In a fruit about 40 mm in length, the enlargement of the cells is so vigorous that the cell walls

disintegrate. At this stage certain groups of small cells are also seen in the mesocarp in between the enlarged cells that are filled with juice. These groups of small cells are formed due to the pressure of the surrounding enlarging cells (Fig. 4).

The author takes this opportunity to record his sincere thanks to Professor V. Puri, Meerut University, Meerut and to Dr. Virendra Singh, Meerut College, Meerut, for their valuable suggestions.

### NEUTRON INDUCED VARIEGATED MUTATION IN TAPIOCA

THIS is a report on a variegated mutant obtained in the neutron irradiated population of tapioca.

Fresh cuttings of a promising tapioca (*Manihot esculenta* Crantz) var. *H-97* (obtained from Dr. N. Hrish, Director, Central Tuber Crops Research Institute, Trivandrum) were exposed to fast neutrons using Standard Neutron Irradiation Facility (SNIF) in the APSARA Reactor of the Bhabha Atomic Research Centre. The dose rate was 71 rad/min and 12 cuttings were exposed per treatment. The radiation dose ranged from 25 to 250 rad. The cuttings along with untreated control were planted in the field immediately after treatment.

One of the two sprouts developing from one cutting in 125 rad treatment was a sectorial chimera with variegated leaves in early growth period in the  $MV_1$  generation. After harvest, the stem which had variegated leaves was made into ten cuttings and planted. In the  $MV_2$  generation, two sprouts in the population had all their leaves variegated; the lobes were light green with white border (Fig. 1). Three other sprouts in early stages of growth were chimeric and had variegated leaves as in the  $MV_1$  generation. One of these sprouts later developed normal green leaves while in the other two, the leaves later developed were variegated. All the other sprouts in the population were normal green.

There is a garden variety of tapioca (*M. esculenta* Crantz var. *variegata* Hort.) which is having variegated leaves with yellow middle region and green border. The variant obtained in the present study is conspicuously different from the existing variegated type with respect to chlorophyll distribution and its nature. On account of low chlorophyll content, the growth was less vigorous in the variegated mutant. As the palisade cells did not possess chlorophyll and were mostly empty the leaves appeared light green especially on the ventral side.

Trombay, Bombay-400 085, August 13, 1974.

### PROTEIN CONTENT IN HEALTHY AND YELLOW MOSAIC INFECTED SOYBEAN SEEDS

DURING a survey of important soybean growing areas of Uttar Pradesh in 1971 and 1972 soybean was found infected with yellow mosaic everywhere, except in the hills. Its incidence varied from 10-30% in different areas. The samples from these areas were collected and studied at University of Gorakhpur. The effect of yellow mosaic disease on protein content of seeds of some important soybean varieties was studied in the present paper.

Four varieties of soybean, viz., Bragg, Clark-63, Lee and Local-2 were selected. For each variety two lots each of 20 seedlings were taken. One lot was treated with white flies (*Bemisia tabaci* Gennadius) already fed on the diseased leaves. The other lot was left healthy. The plants were kept in insect proof conditions. When they attained maturity the seeds were collected separately and subjected to protein estimation which was done by the following method.

One hundred mg of dried seeds were crushed with 10 ml of trichloroacetic acid. This was then centrifuged at 1600 rpm. To the residue 1 ml of digestion mixture (2.4 g of selenium/litre of conc.  $H_2SO_4$ ) was added. It was mixed well and allowed

FIG. 1. Tapioca var. *H-97* and the variegated mutant. A and B—Plant and leaf of parent *H-97*. C and D—Plant and leaf of the Variegated mutant.

to stand for 30 minutes. Four drops of 50% sodium thiosulphate solution followed by 5 ml of another digestion mixture (32 g salicylic acid/litre of conc.  $H_2SO_4$ ) were then added. After the digestion was complete, about 5 drops of 10% perchloric acid was added and the contents were heated slowly till the solution became clear. The solution was then made up to 100 ml. In a colorimetric tube 1 ml of this solution, 8.5 ml of Nessler's reagent and 0.5 ml of gum-ghati solution were added. The contents were mixed thoroughly. The ammonia thus evolved was estimated in 'A.M.I.L.' Biochem. Absorptiometer using filter No. 42.

The value of organic nitrogen thus obtained was then multiplied by a factor 6.25 to obtain total protein content.

The results given in Table I show that yellow mosaic increased the protein content in the seeds in all the four varieties tested. Maximum increase was recorded in the variety Local-2 and it was least in Bragg. The increase was dependent upon the susceptibility of the varieties the most susceptible variety having the maximum protein.

TABLE I

*Protein content in healthy and yellow mosaic infected seeds*

| Varieties | % protein in the healthy seed | % protein in the diseased seed | % increase |
|-----------|-------------------------------|--------------------------------|------------|
| Bragg     | 40.6                          | 43.0                           | 2.2        |
| Clark-63  | 42.5                          | 45.5                           | 3.0        |
| Lee       | 41.2                          | 46.7                           | 5.6        |
| Local-2   | 36.3                          | 42.5                           | 6.9        |

Increased protein content in virus affected plant parts has been reported by some workers<sup>1-6</sup> while some others have reported a reduction in protein content due to virus disease<sup>1,7</sup>.

In the present study protein content of the seeds is increased in all the varieties of soybean affected by yellow mosaic. This increase appears to be due to the increased amount of free amino acids and total nitrogen which have led to an increased rate of protein synthesis through condensation of amino acids.

The authors are thankful to Dr. K. S. Bhargava for providing necessary laboratory and library facilities. They are also grateful to Dr. R. D. Joshi for his helpful suggestions.

#### A NEW LEAF SPOT DISEASE OF *CENTELLA ASIATICA* L.

A SEVERE leaf spot disease of *Centella asiatica* L. was observed during summer season around Madanapalle in Chittoor District. The disease manifests itself in the form of leaf spots which are elongated or circular, yellowish brown when young and becoming dark brown with age, with a greyish white centre bordered by deep brown margin. In cases where the infection starts from the apex of the leaf the patch may extend and cover about half of the lamina (Fig. 1).

FIG. 1

The fungus was isolated in pure culture from the necrotic spots of the leaves and on inoculation to healthy leaves proved to be a virulent pathogen. The organism consistently produced the typical symptoms and its morphological and cultural characteristics were exactly similar to the previous isolate.

The fungus grew and sporulated well on PDA medium. Mycelium grey coloured with green pigment deposited on the medium. The hyphae septate, branched and measured  $3-6\mu$  in width. Only conidiophores and conidia were produced. Conidiophores dark brown, unbranched and erect. Conidia clavate, slightly bent or curved, rarely triangular with flattened ends,  $2-4$  celled ( $1-3$  septate), light brown in colour and measured  $12$  to  $21 \times 2$  to  $9\mu$ . One or two of the middle cells were disproportionately enlarged and more darkly coloured than the end cells.

The causal agent has been identified and confirmed as the *Curvularia* state of *Cochliobolus geniculatus* Nelson (IMI 184580).

Thanks are due to Dr. M. B. Ellis, Commonwealth Mycological Institute, Kew, England, for identifying the pathogen and to Prof. V. S. R. Das for providing facilities.

### MEALY BUGS ON THE ROOTS OF *PARTHENIUM* WEED

*Parthenium hysterophorus* Linn., commonly called "congress grass" is at present an aggressive weed in many parts of India. It is not known to be affected by any pest or disease<sup>1</sup>. Recently, Anupam Varma *et al.*<sup>2</sup> have reported mycoplasmal etiology for this plant growing at Delhi and proposed its utility for the biological control. In some plants

of the same species growing at Mysore City, attack of mealy bugs was observed on their roots. Young plants were especially prone to the attack and later they died. Such plants were seen wilted. The nymphs and adult females lodge on the root surface and feed on them (Fig. 1). The bug is identified

FIG. 1. Roots of *Parthenium* infected with mealy bugs.

as *Ferrisia virgata* Cockerell. Further search for other pests attacking the plant is essential for finding out their use in biological control of this pernicious weed.

We thank Mrs. L. Huddleston, British Museum (Natural History), London and Dr. G. P. Chenna-Basavanna, Professor of Entomology, UAS, Bangalore, for identification of the mealy bug.

## SHORT SCIENTIFIC NOTES

### Discovery of Phosphorite in the Palaeocene Eocene Rocks of Northwestern Himalayas

During the course of investigations of the project "Prospecting of Phosphorite in Northwestern Himalayas", the authors discovered a number of phosphate bearing horizons in the Palaeocene-Eocene sediments exposed in the vicinity of Nahan (Sirmur District, Himachal Pradesh). Concentration of phosphatic material is observed in olive green shales, brownish green siltstones and pale brown limestones. Dark grey coloured phosphatic nodules having diameter up to 10 cm occur in crushed carbonaceous matter. The phosphatic nodules assay as high as 26.16%  $P_2O_5$ . The phosphatic material occurs in the form of pellets ranging in size from minute microscopic to over 10 mm, void filling, intimately intermixed with matrix and as nodules. The phosphate bearing beds extend in the strike direction for a considerable length and warrant serious attention.

The only known occurrence of phosphatic material in the Palaeocene-Eocene rocks of Himachal Pradesh is from Mahasu District (Aggarwal<sup>1,2</sup>; Chaudhri<sup>3</sup>). Detailed work is in progress.

### *Neanotis montholoni* (Hook. f.) W. H. Lewis: A New Record for Andhra Pradesh

*Neanotis montholoni* (Hook. f.) W. H. Lewis, (Rubiaceae) was first collected in September, 1968 from Kamareddy, Andhra Pradesh. It was identified by the Royal Botanic Gardens, Kew and deposited there. Duplicates are deposited with (CAL.) and (BLATT.) under voucher No. Bahadur 105.

The species hitherto known to occur, only in the South-West Indian hills is an addition to the flora of Andhra Pradesh. This collection from a place far from its original place of collection, i.e., Concan and Southwards (HK. f., *Fl. Brit. India*, 3 : 73, 1880), Mysore and Canara to Malabar (Gamble, *Fl. Madras*, 2 : 427, Rep. 1967), Concan, Poona, Belgaum (Cooke, *Fl. Bombay*, 2 : 22, Rep. 1967).

The present collection suggests the possibility of a very wide range of its distribution. Further, the species which is characteristic of higher elevations (2,600 m above sea level) is now being found at sea level. The following herbarium specimens have been examined which suggest wider distribution of this species in the plains of Maharashtra and the adjoining border districts of Andhra Pradesh where from Kamareddy is very close.

Ellichpur, Central Provinces and Berar, 15-12-1894, G. Watt, 15392 (CAL.), Bhausa, Narsinpur District, Plateau of Deccan, 13-8-1903, Kalka Pershad, 15393 (CAL.) Khandwa, Nimar District, 23-9-1908, I.H. Burkill, 31005 (CAL.), Nasik Road, Nazik District, 11-9-1910, D. Hooker, 3446 (CAL.).

The species flowers and fruits from August to November. The mode of dispersal and distribution is not known but could be due to wind or water as the seeds are light.

My grateful thanks to Sir George Taylor for providing the identification and to Dr. D. B. Deb for the loan of *Anolis* material and Prof. U. B. S. Swami for encouragement.

Warangal 506001, A.P., September 30, 1974.

### Studies on the Association between Azotobacter Population and Asymbiotic Nitrogen Fixation in Calcareous Soils of Pusa, Bihar

The present investigation was undertaken to study the association between azotobacter population and asymbiotic nitrogen fixation in calcareous soils.

The population of azotobacter was estimated by plate dilution method in Jensen's medium (Allen, 1957). With a view to establishing the gain in the amount of nitrogen, one gram of the soil was incubated in 100 ml of Ashby's mannite broth medium for 21 days and the amount of nitrogen fixed asymbiotically by azotobacter was estimated by Kjeldahl's method. A control with one gram of soil under similar condition was also run to calculate the gain in amount of nitrogen. The results have been shown in Table I.

The highest population of azotobacter was found in silty loam followed by sandy loam, silty clay loam and clay loam soils. The lowest count was noted in clayey soils. It will be further seen that

TABLE I

| Soil type          | Average<br>azoto-<br>bacter<br>count<br>(10 <sup>5</sup> ) | Amount of<br>nitrogen in mgm |         | Gain in<br>nitrogen<br>in mgm<br>per gram<br>soil |
|--------------------|--|------------------------------|---------|---|
|                    |  | Treat-<br>ed                 | Control |   |
| 1. Silty loam      | 22.58  | 8.02                         | 1.30    | 6.72  |
| 2. Sandy loam      | 15.83  | 6.61                         | 1.19    | 4.42  |
| 3. Salty clay loam | 14.80  | 4.95                         | 1.52    | 3.43  |
| 4. Clay loam       | 7.20   | 4.05                         | 0.97    | 3.07  |
| 5. Clay            | 5.66   | 4.02                         | 1.24    | 2.78  |

the gain in amount of nitrogen varied directly with azotobacter population, the correlation coefficient between counts of azotobacter in different soil types and amount of gain in nitrogen being positive and significant at less than 5% level ( $r = 0.899$ ).

### Pythium Stalkrot—A Deadly Disease of Maize in India

Pythium stalkrot of maize incited by *Pythium aphanidermatum* (Edson) Fitzp. (= *P. butleri* Subr.) was first reported in India by Srivastava and Rao (1964) and after release of hybrids and composites, the disease appeared in epidemic proportions in certain parts of India.

The disease attacks the crop during July–August in Kharif season and its occurrence has been recorded from various locations in Delhi, Punjab, Haryana, Himachal Pradesh, Bihar, Uttar Pradesh and Andhra Pradesh. In 1969, the disease assumed epidemic proportions at Sundergarh (Himachal Pradesh) and the incidence was recorded upto 40% which severely damaged the crop.

The experiments conducted during 1967–71 at IARI, New Delhi, have revealed that the Pythium stalkrot of maize occurs when the vulnerable pretasseling stage of crop, coupled with high plant population per unit area in a poorly-drained field coincides, with high atmospheric temperature (30–35°C) and high relative humidity (90–100%) as prevalent in the month of August.

The following control measures are suggested to combat this menace:

- (i) Comparatively tolerant hybrids and composites like Him-123, Hi-starch and Vijay should be selected for planting.
- (ii) Regulation of planting time either before first week of June or after second week of July.
- (iii) Plant population should not to exceed 50,000 plants per hectare,
- (iv) Proper field drainage to be maintained to avoid waterlogging.
- (v) Previous crop residue or debris to be removed to avoid the chances of the buildup of the pathogen thereupon,
- (vi) Balanced fertilizer application at the rate of 120 kg nitrogen, 50 kg phosphorus and 50 kg potassium.
- (vii) Soil drenching with 2% solution of Captan at the rate of 1000 litres per acre at preflowering stage of crop,
- (viii) Excessive organic manuring not be resorted to.

The authors are thankful to Dr. S. P. Raychaudhary, Head of the Division of Mycology and Plant Pathology, Indian Agricultural Research Institute, New Delhi-12, for providing the facilities to carry out these investigations.

### Pathology of Chlamydial Abortions in Ovine and Caprine

A storm of late abortions in sheep and goats (77 sheep and 3 goats) alongwith premature birth of weak off-springs were proven to be due to chlamydial agent for the first time in India.

The majority of cases had necrosed placental cotyledon and acute exudative placentitis. Generalised congestion with enlargement of spleen and liver was present in some foetuses. Liver was most commonly involved having perivascular reticuloendothelial cell proliferations and degenerative foci. Presence of elementary bodies in the smears of placentae, foetal organs, thoracic and abdominal fluid was demonstrated by Macchiavello and Gimenez stains. These observations are in

conformity with the previous workers<sup>1,2</sup>. Gliosis in brain of aborted foetuses was an additional feature necessitating further studies.

In parallel with histo-anatomical studies isolation of the chlamydial agents in the yolk sac of embryonating chicken eggs confirmed the disease as chlamydiosis.

Complement fixing antibodies in 21 days post-abortion sheep sera were demonstrated with standard chlamydial group antigen and antigen prepared presently.

The immunofluorescence studies with the group specific conjugated globulin confirmed these organisms in the sections of cotyledon and yolk sac membrane as Chlamydia.

Authors thank Dr. J. Storz and Dr. L. Blanco for supplying the antigen and group specific conjugate. The facilities provided by Dr. C. M. Singh, Director of this Institute are also acknowledged.

### Occurrence of Spontaneous Haploid in *Ricinus communis* L. var. Aruna

Haploid has been reported in castor—*Ricinus communis* L.— by Poole and Hadley<sup>1</sup> from selfed seed of P.I. 183468. There are reports of haploids in other crop plants reviewed by Kimbar and Riley<sup>2</sup> and Magoon and Khanna<sup>3</sup>. Since 1954 there has been no report about haploid in castor and the work developed from such a plant in developing homozygous diploid line. Present paper deals with the haploid obtained in *Ricinus communis* variety Aruna.

In Aruna at Regional Research Station, Raichur, India, an interesting plant was observed. This plant was dwarf with a few rough and narrow leaves and

produced spike under field conditions which did not set any seed. The plant was dug out and potted in the bigger pot. Transplanting had enormous effect on the plant by way of producing plenty of foliage and production of spikes in addition to the primary ones. Cytology of the plant revealed in root tip preparations following oxyquinoline technique that it possessed ten somatic chromosomes as compared to the twenty that are seen in the normal plants. Flower buds were used for meiotic study which also showed ten univalents. Spikes produced from the haploid plant possessed shrivelled seeds. In order to develop homozygous diploid from the haploid, the secondary branches have been treated with various concentrations of aqueous colchicine (0.1 to 0.5%) to develop inbred lines for use in commercial hybrid seed production. However the attempt was not successful in obtaining homozygous diploids. Studies in castor show that the utilisation of heterosis seems to have limited scope in hybrids of the varieties HC 6, Gujarath Monospoke, Cimmarron Inbred, Aruna, Rosy and TMV 11. However the development of homozygous diploid lines as is envisaged might help in developing commercial hybrids. The said haploid is surviving showing perennial habit. Attempt of diploidizing has been continued.

The authors take the opportunity of thanking Dr. J. V. Goud and Dr. N. B. Kajjari for encouragement and providing facilities.

## ABSTRACT

The fossil fission track technique has been used in dating Precambrian muscovite samples of Bihar Mica Belt (Kodarma, District Hazaribag). The average age obtained for this belt is  $865 \pm 72$  million years which agrees with the age determined by radiometric methods.

## INTRODUCTION

**T**HE fossil fission track technique was introduced by Price and Walker (1963) for dating of rocks and mineral samples of geological origin. It utilises the fact that uranium is present in almost all the minerals and it undergoes spontaneous fission at a rate much slower than its usual disintegration through  $\alpha$ -decay. The fission fragments which are produced travel inside the mineral leaving their tracks as radiation damaged regions. These tracks are of thickness 100 Å and can be directly observed under an electron microscope<sup>1</sup>. However, they can be observed under an optical microscope<sup>2</sup> by etching the tracks with suitable chemical reagents.

**Theory.**—The formula used for calculating the age of the samples of Precambrian origin has been derived by Price and Walker<sup>3,5</sup>. It has been applied with success by Mehta and Nagpaul<sup>6</sup>.

The density  $\rho_s$  of fossil fission tracks due to spontaneous fission of  $U^{238}$  present on any cleaved surface is given by

$$\rho_s = \frac{n_{238} \lambda_f R_0 (e^{\lambda_d T} - 1)}{2 \lambda_d} \quad (1)$$

where  $n_{238}$  is the number of  $U^{238}$  atoms/c.c. of the mineral,  $\lambda_f$  and  $\lambda_d$  are constants for spontaneous fission and  $\alpha$ -decay respectively,  $R_0$  is the combined range of fission fragments in mineral and  $T$  is the time since the sample started registering the tracks after it was crystallised.

The concentration of  $U^{238}$  in the sample is determined by measuring the concentration of  $U^{235}$ , which is done by irradiating the sample with a known dose of thermal neutrons in a nuclear reactor and measuring the density  $\rho_i$  of induced fission tracks on a newly cleaved surface.

$$\rho_i = n_{235} \sigma \phi R_0 / 2 \quad (2)$$

where  $n_{235}$  is number of  $U^{235}$  atoms/c.c. of mineral,  $\sigma$  is cross section for thermal neutron capture and  $\phi$  is the integrated (nvt) thermal neutron dose.

Eliminating  $R_0$  from (1) and (2),

$$T = \frac{1}{\lambda_d} \log_e \left( 1 + \frac{\rho_s I \phi \sigma \lambda_d}{\rho_i \lambda_f} \right) \quad (3)$$

where  $I$  is isotopic abundance of  $U^{235}$ . The values of various constants of eqn. (3) are:

$$\lambda_f = 7.03 \times 10^{-17} \text{ yr}^{-1}$$

$$\sigma = 582 \times 10^{-24} \text{ cm}^2$$

$$I = 7.26 \times 10^{-3}$$

$$\lambda_d = 1.52 \times 10^{-10} \text{ yr}^{-1}$$

Substituting these values, the eqn. (3) reduces to age formula

$$T = 6.57 \times 10^9 \log_e \left( 1 + 9.25 \times 10^{-18} \frac{\rho_s}{\rho_i} \phi \right) \quad (4)$$

**Experimental Details.**—The muscovite samples selected for this study have been collected from the mica mines of Kodarma, District Hazaribag (Bihar). The tight books of muscovite were chosen, washed and cleaved along the horizontal plane to expose fresh surfaces for etching of radiation damage. The samples were cut to the dimensions 2 cm.  $\times$  1.5 cm.  $\times$  200  $\mu$ m.

The samples are etched by immersing them for 1 hour in 48% HF at room temperature. The radiation damaged portions are attacked by chemical action and after washing and drying of samples the fossil fission tracks can be observed under the optical microscope using a magnification of 300–600 $\times$ . The tracks appear as dark black rods and can be easily counted to find the surface density  $\rho_s$ . Care should be taken to count the tracks only on the cleaved surface without going inside the sample.

To determine the induced fission track density  $\rho_i$ , the samples are prepared from the original tight books of muscovite, washed with de-ionised water and alcohol respectively and packed in lexan bags to fit a cylinder of diameter 1.6 cm and of length 3.5 cm. These samples are sent to the Isotope Division, B.A.R.C., Trombay, for irradiation with an integral neutron dose of  $10^{18}$  which is determined by enclosing a calibrated glass dosimeter along with the samples.

The induced fission of  $U^{235}$  takes place and the fission fragment tracks are deposited inside the samples as well as the glass dosimeter. The samples are etched as previously and the surface

density  $\rho_i$  of induced fission tracks is determined. The glass piece is fractured to expose the fresh surface and etched in 20% HF for 30 seconds at room temperature. The surface density  $\rho$  of etch pits is measured and the integral neutron flux  $\phi$  is calculated by using the calibration relation<sup>7</sup>,

$$\phi = 2.26 \times 10^{11} \rho \quad (5)$$

**Results.**—From the measured values of  $\rho_s$ ,  $\rho_i$  and  $\phi$ , the fission track ages of muscovite samples have been calculated from relation (4). The results are summarized in Table I. It is evident that the

TABLE I

## THERMAL DECOMPOSITION KINETICS

### Part VI\*. An Absolute-Rate-Theory-Based Equation for the Evaluation of Kinetic Parameters from Nonisothermal Thermogravimetry

C. G. R. NAIR AND P. M. MADHUSUDANAN

Department of Chemistry, University of Kerala, Trivandrum 695001

#### ABSTRACT

A new equation, taking into account the temperature-dependence of the pre-exponential factor based on the absolute rate theory of reactions, is proposed for the evaluation of kinetic parameters of solid-state reactions from nonisothermal thermogravimetric data.

THE rate equation widely used by different workers in nonisothermal thermogravimetry (TG) can be put in the form<sup>6</sup>

$$da/dT = (A/\phi) (1 - a)^n \exp(-E/RT) \quad (1)$$

where  $a$  = fraction decomposed at temperature  $T$ ,  $\phi$  = heating rate,  $A$  = pre-exponential term,  $R$  = gas

constant and  $E$  = energy of activation. In integrating eq. (1) it has always been assumed that  $A$  is temperature-independent<sup>7-11</sup>. Ingraham and Marier point out that this assumption is not rigorously valid<sup>12</sup>. A critical review of this aspect has recently been made by Gyulai and Greenhow<sup>13</sup>. In this communication, we wish to present the derivation of a more accurate equation taking into account the temperature-dependence of  $A$ .

\* For Parts I to V, see references 1 to 5.

## DERIVATION

According to the theory of absolute reaction rates, the temperature-dependence of  $A$  is given by the relation,

$$A = (kT/h) \exp(\Delta S/R) \quad (2)$$

where  $k$  = Boltzmann constant,  $h$  = Planck constant,  $\Delta S$  = entropy of activation. Combining eqs. (1) and (2), we get,

$$da/dT = [(k/h\phi) \exp(\Delta S/R)] \times \left[ T \exp\left(-\frac{E}{RT}\right) \right] (1-a)^n \quad (3)$$

Eq. (3) will be most useful in its integrated form. The integration may be done as follows:

Substituting

$$y = (k/h\phi) \exp\left(\frac{\Delta S}{R}\right)$$

and

$$x = E/RT$$

in eq. (3), rearranging it and putting in the integral form (limits for  $a$  and  $T$  being 0 to  $a$  and 0 to  $T$  respectively), we get

$$\int_0^a da/(1-a)^n = (YE^2/R^2) \int_x^\infty x^{-3} e^{-x} dx \quad (4)$$

The R.H.S. of eq. (4) is a special case of the most general form of the incomplete gamma function<sup>14</sup>. Eq. (4) on integration gives

$$\frac{1 - (1-a)^{1-n}}{1-n} = \frac{YE^2}{R^2} e^{-x} x^{-3} \left(1 - \frac{3}{x}\right) \quad (5)$$

Here the series term in R.H.S. has been terminated with the second term. Putting the L.H.S. as  $g(a)$  and re-introducing the values of  $x$  and  $Y$  eq. (5)

$$g(a) = (k/h\phi) \exp(\Delta S/R) \frac{RT^3}{E} \left(1 - \frac{3RT}{E}\right) \times \exp\left(-\frac{E}{RT}\right) \quad (6)$$

Taking logarithms,

$$\log\left(\frac{g(a)}{T^3}\right) = \log\left[\frac{kR}{h\phi E} \left(1 - \frac{3RT}{E}\right)\right] + \frac{\Delta S}{2 \cdot 303R} - \frac{E}{2 \cdot 303RT} \quad (7)$$

Graphical Evaluation of  $E$  and  $\Delta S$  from Eq. (7)

Two approaches are possible here:

(a) As in the Coats-Redfern equation, where  $2RT/E$  is assumed to be negligible compared to unity, one may assume that the same holds good for the term  $3RT/E$ . Then, eq. (7) reduces to:

$$\log\left[\frac{g(a)}{T^3}\right] = \log\left(\frac{kR}{h\phi E}\right) + \frac{\Delta S}{2 \cdot 303R} - \frac{E}{2 \cdot 303RT} \quad (8)$$

A plot of L.H.S. versus  $1/T$  would now be linear, with slope equal to  $-E/2 \cdot 303R$ . The value of  $\Delta S$  may be got from the intercept.

(b) The R.H.S. of eq. (7) may be rearranged in the form

$$\log\left(\frac{kR}{h\phi E}\right) + \frac{\Delta S}{2 \cdot 303R} + \left[\log\left(1 - \frac{3RT}{E}\right) - \frac{E}{2 \cdot 303RT}\right] \quad (9)$$

where the terms involving variable  $T$  have been segregated into the expression within the square bracket. This expression can be put in the form (here  $x = E/RT$ ):

$$\left[\log\left(1 - \frac{3}{x}\right) - \frac{x}{2 \cdot 303}\right] \quad (10)$$

This may be linearised by using the method of least squares, giving various values for  $x$  ranging<sup>15</sup> from 20 to 100. This gives

$$\log\left(1 - \frac{3}{x}\right) - \frac{x}{2 \cdot 303} = -0.0629 - 0.4337x \quad (11)$$

Resubstituting for  $x$ , we may now rewrite eq. (7) as

$$\log\frac{g(a)}{T^3} = \log\frac{kR}{h\phi E} + \frac{\Delta S}{2 \cdot 303R} - 0.0629 - \frac{0.4337E}{RT} \quad (12)$$

A plot of L.H.S. versus  $1/T$  would now be linear, from whose slope and intercept,  $E$  and  $\Delta S$  respectively may be evaluated. A further mathematical simplification may, if desired, be effected by taking over the  $T^3$  term also to the R.H.S. of eq. (7) and linearising, to give

$$\log g(a) = \log\frac{kE^2}{h\phi R^3} + \frac{\Delta S}{2 \cdot 303R} - 3.7958 - \frac{0.4582E}{RT} \quad (13)$$

## Comparison with the Coats-Redfern Equation

It is interesting to compare eq. (7) with the equation developed earlier by Coats and Redfern<sup>7</sup>, who did not take into account the temperature-dependence of  $A$ . The Coats-Redfern equation can be put in the following form:

$$\log\left(\frac{g(a)}{T^2}\right) = \log\left[\frac{AR}{\phi E} \left(1 - \frac{2RT_g}{E}\right)\right] - \frac{E}{2 \cdot 303RT} \quad (14)$$

or

$$\log\left(\frac{g(a)}{T^2}\right) = \log\left[\frac{kRT_g}{h\phi E} \left(1 - \frac{2RT_g}{E}\right)\right] + \frac{\Delta S}{2 \cdot 303R} - \frac{E}{2 \cdot 303RT} \quad (15)$$

It may be seen that equations (15) and (7) are generally of the same form. But, eq. (7) has the following advantages over eq. (15).

1. Eq. (7) has a more rigorous treatment and takes account of the temperature-dependence of  $A$ . At the same time, it involves just the same type of computational work as eq. (15).

2. Eq. (7) avoids the arbitrariness with which eq. (15) introduces the temperature term in the expression for

$$A = \frac{kT}{h} e^{\Delta S_{IR}}$$

the  $T$  in this expression has been variously and arbitrarily chosen as  $T_s$  (the DTG peak temperature)<sup>2</sup> or  $\bar{T}$  (the average temperature)<sup>16</sup>.

The improvement effected by the present equation may be illustrated by considering a theoretical TG curve. Such a procedure has been suggested by Sestak in a different context<sup>17</sup>. A theoretical TG curve with an assumed value of  $E = 120$  kJ mole<sup>-1</sup> was used for this purpose. Here, the Coats-Redfern equation gives a value  $E = 123.3$  kJ mole<sup>-1</sup> whereas the present equation gives a value  $E = 119.8$  kJ mole<sup>-1</sup>. The improvement is obvious.

#### ACKNOWLEDGEMENT

## TWO UNUSUAL FLAVONES (ARTEMETIN AND 7-DESMETHYL ARTEMETIN) FROM THE LEAVES OF *VITEX TRIFOLIA*

A. G. RAMACHANDRAN NAIR, P. RAMESH AND S. SANKARA SUBRAMANIAN

Department of Chemistry, Jawaharlal Institute of Post-Graduate Medical Education and Research, Pondicherry 605006

#### ABSTRACT

Adsorption chromatography on silica gel of the chloroform extract of dry leaves of *Vitex trifolia* (Verbenaceae) has yielded two methylated flavones of rare occurrence. Based on chemical as well as UV, IR, PMR and Mass spectral data, the major compound has been characterised as 5, 7-dihydroxy-3, 3', 4', 6-tetra methoxy flavone (3, 3', 4', 6-tetra methyl quercetagenin) and the minor as artemetin (5-hydroxy-3, 3', 4', 6, 7-penta methoxy flavone) by direct comparison with authentic sample. The earlier observation regarding the variation of flavonoid pattern with reference to plant geography in *Vitex* is further supported by our results.

THE distribution of flavonoids in the genus *Vitex*<sup>1</sup> under the family Verbenaceae and the Natural Order Tubiflorae is interesting especially with reference to the glycoflavones (atypical in this family) and the unusual flavones like casticin (3, 4', 6, 7-tetra methyl quercetagenin), and certain variations in the flavonoid patterns relating to plant geography have been observed. Some significance is also attached to these flavonoids in the classification of plants of this family.

In continuation of our work on the flavone glucuronides of the Verbenaceae<sup>2</sup>, we have made a

detailed chemical examination of the flavonoids of the leaves of *Vitex trifolia* Linn. earlier recorded to contain casticin<sup>3</sup> and vitexin<sup>4</sup>, and our results are recorded here.

The dry leaves of *V. trifolia* were first extracted with hot  $\text{CHCl}_3$  and then with MeOH. The concentrated  $\text{CHCl}_3$  extract was chromatographed on a column of silica gel using petroleum ether, benzene and  $\text{CHCl}_3$  as eluting solvents. No crystalline flavonoid was obtained from petrol eluates.

The residue from the benzene fraction on recrystallisation from  $\text{Me}_2\text{CO-MeOH}$  yielded a small

amount of light yellow needles of a flavone, m.p. 162–63°,  $\lambda_{\max}$  254, 274 sh. 346 nm. (MeOH). It was purple under U.V. and U.V./NH<sub>3</sub>. It gave an olive green colour with Fe<sup>3+</sup> and yielded quercetagenin on demethylation with Ac<sub>2</sub>O and HI. It had  $R_f$ : 0.36 (15% HOAc), 0.78 (30% HOAc), 0.85 (50% HOAc), 0.95 (BAW), 0.92 (phenol), 0.96 (Forestral) and 0.96 (*t*-BAW). It was identified as 5-hydroxy-3, 3', 4', 6, 7-penta methoxy flavone (artemetin<sup>5,6</sup>) and the identity further confirmed by direct comparison including co-PC with an authentic sample. A minute quantity of a flavone present in the mother liquor was fluorescent light blue under U.V. and U.V./NH<sub>3</sub> and did not give any colour with Fe<sup>3+</sup>. It was identified as 5-methyl artemetin (quercetagenin hexa methyl ether) by direct comparison with a synthetic sample prepared by complete methylation of quercetagenin.

The residue from the CHCl<sub>3</sub> fraction was thrice recrystallised from Me<sub>2</sub>CO–MeOH, when a pale yellow flavone, m.p. 168–69° was obtained. It gave yellow colour with NH<sub>3</sub> and greenish blue with Fe<sup>3+</sup>. It was deep purple under U.V. and U.V./NH<sub>3</sub> and had  $\lambda_{\max}$ : 256, 271 sh. 340 (MeOH); 256, 271, 344 (NaOAc); 266, 282 sh. 297 sh. 368 (AlCl<sub>3</sub>) and 257, 272, 342 (NaOAc/H<sub>3</sub>BO<sub>3</sub>) almost the same as artemetin. The PMR spectrum (CDCl<sub>3</sub>) showed signals ( $\delta$  values, ppm) at 3.98, 3.95, 3.90 and 3.88 (each singlet of 3 protons due to –OCH<sub>3</sub>), 6.5 (singlet, 8–H), 6.63 (doublet,  $J = 9$  cps, 5–H) 7.66 (multiplet, 2–H and 6'–H) and a low field proton at 12.3 (5–OH) and the IR (KBr) exhibited absorption bands (cm<sup>-1</sup>) at 3640 (–OH), 1670 (conjugated C=O), 1610, 1590, 1560 and 1520 (benzene derivative). The mass spectrum of the compound showed the parent ion at  $m/e$  374 ( $M^+$ , C<sub>19</sub>H<sub>18</sub>O<sub>8</sub>, 100%) and fragmentation ions at 373 ( $M^+-H$ , 24%), 359 ( $M^+-CH_3$ , 33%), 346 ( $M^+-CO$ , 2%), 344 ( $M^+-2CH_3$ , 5%), 331 ( $M^+-CH_3CO$ , 10%), 187 ( $M^+$ , 20%) and 173 ( $M^+-2H$ , 35%) and 182, 167, 161, 151, 139, 137 and 123 (due to ions of RDA fragmentation and further cleavage). The PMR and mass spectral data along with the  $R_f$  (0.20, 0.56, 0.79, 0.92, 0.92, 0.93 and 0.94 resp. in the above solvents) clearly indicated the compound to be a dihydroxy-tetra methoxy flavone. On acetylation with Ac<sub>2</sub>O and pyridine, it yielded a crystalline diacetate, m.p. 174–75°, whose mass spectrum showed the parent ion at  $m/e$  458 ( $M^+$ , C<sub>23</sub>H<sub>22</sub>O<sub>10</sub>, 11.5%) and fragmentation ions at 457 ( $M^+-H$ , 14%), 443 ( $M^+-CH_3$ ), 428 ( $M^+-2CH_3$ ), 415 ( $M^+-CH_3CO$ , 100%), 400 [ $M^+-(CH_3CO+CH_3)$ , 23%], 385 [ $M^+-(2CH_3+CH_3CO)$ ] 372 ( $M^+-2CH_3CO$ , 35%) and 342 [ $M^+-(2CH_3+2CH_3CO)$ ] confirming the dihydroxy tetra methoxy flavone structure,

On demethylation with HI and Ac<sub>2</sub>O, it gave 3, 3', 4', 5, 6, 7 hexahydroxy flavone (quercetagenin). From these data, the flavone was identified as a tetra methyl ether of quercetagenin. The almost identical UV spectra of the compound and artemetin, and the mass fragmentation pattern established the structure as 5, 7-dihydroxy-3, 3', 4', 6-tetra methoxy flavone. (The 7-OH of a 6-methoxylated flavone has been recorded<sup>7,8</sup> to behave in such a manner as to miss its detection by U.V. analysis). The identity was finally confirmed by a partial synthesis of artemetin from our sample by selective methylation using Me<sub>2</sub>SO<sub>4</sub> and anhydrous K<sub>2</sub>CO<sub>3</sub> for 6 hr. (Selective methylation using Me<sub>2</sub>SO<sub>4</sub> and KHCO<sub>3</sub> for 12 hr was not successful, which may again be attributed to the peculiar nature of 7-OH in 6-methoxylated flavones).

The pigment from MeOH concentrate was identified as luteolin by  $\lambda_{\max}$ ,  $R_f$ , preparation of its tetraacetate and direct comparison with an authentic sample. No flavone glycoside could be detected.

Our isolation of artemetin and 5, 7-dihydroxy-3, 3', 4', 6-tetramethoxy flavone (7-desmethyl artemetin) in the place of casticin and vitexin reported earlier in *V. trifolia* confirms the observation of Harborne<sup>1</sup> of the variation of flavonoid pattern in relation to plant geography in this genus. Artemetin has been earlier isolated from the leaves<sup>9</sup> and seeds<sup>10</sup> of *V. negundo*. Ours is the second report of the isolation of the unusual flavone, 7-desmethyl artemetin, the first being from *Bahia oppositifolia*<sup>11</sup> (Compositae).

We are grateful to Shri N. P. Balakrishnan, Regional Botanist, Botanical Survey of India, Port Blair for the supply of authentic plant material. Our thanks are due to Prof. T. J. Mabry, University of Texas, Austin, U.S.A. and Prof. T. R. Govindachari, CIBA Research Centre, Bombay, for spectral data, Dr. M. S. Chadha, Bhabha Atomic Research Centre, Trombay, for an authentic sample of artemetin and the Principal, JIPMER, for encouragement.

## AEROPALYNOLOGICAL STUDIES OF BANGALORE CITY

### Part I. Pollen Morphology of *Parthenium hysterophorus* Linn.

SHRIPAD N. AGASHE AND PRATHIBHA VINAY

Department of Botany, Central College, Bangalore University, Bangalore 560001

**B**ANGALORE CITY, known for its salubrious climate almost throughout the year, is often referred to as the air-conditioned City of India. However, the atmosphere of the City is full of pollen pollutants. This fact has great bearing on the different types of pollen allergies, much prevalent in this City.

A comprehensive research scheme has been undertaken by the authors to tackle the pollen allergy problem from palynological point of view. As a prerequisite to this research project, construction of pollen flora based on the collection of pollen from plants growing in the City has been undertaken.

Of late several reports have been published on allergic manifestations of the recently introduced notorious weed, commonly referred to as Congress Weed or White Top, and botanically known as *Parthenium hysterophorus* Linn. It has been further reported that the food grains imported into India from U.S.A. and Canada were contaminated with the seeds of this weed<sup>1,2</sup>. Several methods of eradication of this fast spreading weed, have been suggested recently by Vartak<sup>3</sup> and Jayachandra<sup>4</sup>.

*Parthenium hysterophorus* Linn., a member of the family Compositae, is known to produce pollen abundantly. The toxic effects of the pollen grains of this weed with reference to allergies have been reported by Wodehouse<sup>11</sup>, Shivpuri *et al.*<sup>5,7</sup>. The flowers of this weed known to be amphiphilous. The prevalence of these pollen grains in the atmosphere has been reported by the Aeropalynological work carried on by Shivpuri *et al.*<sup>7</sup> at Delhi and the same has been confirmed by us at Bangalore.

The pollen grains of *P. hysterophorus* were studied by using the standard palynological techniques of Erdtman<sup>2,3</sup> and were found to be very interesting morphologically. Literature indicated that detailed pollen morphology of this weed has not been worked out. Hence the diagnosis of the pollen grains of this weed has been presented here.

### Pollen diagnosis of *P. hysterophorus* Linn.

(Figs. 1-4)

Pollen grains 3-colporate (poritreme), oblatespheroidal ( $16 \times 17 \mu$ ). Apocolpium diameter about  $3.5 \mu$ . Colpi ( $10 \times 2 \mu$ ) tenuimarginate, with tapering ends, membrane smooth.

Ora circular (diameter about  $2 \mu$ ). Exine (spinules included) about  $4.4 \mu$  thick. Sexine about  $3 \mu$  thick, pertectate supratrigillate, provided with pointed spinules. Tegillum undulating, differentiated into supra and infrategillar layers, each less than  $0.5 \mu$  high, supporting the tegillum of each layer. Spinules about  $2 \mu$  high with pointed solid apices, base about  $2.2 \mu$  wide made up of slender rod like elements. Nexine as it seems, consists of a homogeneous layer, inner margin smooth. There appears to be a thin distinct region about less than  $0.5 \mu$  wide between the baculate layer and the nexine.

**Discussion and Summary.**—The family Compositae is referred to as a Eurypalynous family because of the great variety of pollen types found in its members. As far as pollen morphology of *P. hysterophorus* is concerned, except Wodehouse's<sup>10</sup> casual reference, no detailed description is available in the literature surveyed so far. Taking into consideration the pollen characters, Wodehouse's<sup>10,11</sup> supports the view expressed by Bentham and Hooker (1873) who state that phylogenetically Ambrosieae (ragweed tribe) shows a close relationship with the tribe Helianthae through Melampodinae, a sub tribe of Helianthae including *Parthenium* and *Parthenice*.

Considering the views expressed by Wodehouse and our observations of the pollen morphology of *P. hysterophorus* in which the grains are typically 3-colporate, oblatespheroidal, spinulose, a characteristic feature of the majority of the members of Helianthae (Sunflower tribe) and the Ambrosieae, it can be concluded that the tribes Helianthae and

FIGS 1-4. Pollen grains of *Parthenium hysterophorus* Linn. Fig. 1. Diagrammatic representation of the exine stratification, (a) Spindle, (b) supporting bacula of the suprategillum, (c) supporting bacula of infrategillum, (d) thin region inbetween the baculate layer and the nexine, (e) nexine. Fig. 2. Diagrammatic representation of the pollen

granum in apical view showing the apertures, aperture in apical view. Fig. 3. Photomicrograph of the equatorial view showing the aperture and the apertures. Fig. 4. Photomicrograph of the grain in apical view.

Amforaceae are closely related through Melanopodaceae including *Parthenium* and *Parthenium*.

Similarly, the presence of a thin distinct region inbetween the nexine and the baculate layer as shown by Raj in the pollen grains of *Helianthus annuus* Linn. is also noticed by us in the pollen grains of *P. hysterophorus*. Wodehouse<sup>10</sup> while comparing the grains of *Parthenium molle* and *Parthenium* states that they are trigonate with long furrows reaching almost from pole to pole. However, in the illustration of *Parthenium molle* given by him, a clear corporate condition is seen.

The present investigation has brought forth a clear idea of the pollen morphology of the weed *P. hysterophorus* which according to Shrivastava and Kartar Singh<sup>7</sup> is known to cause skin allergies. However, further work is needed to find out the representation of pollen grains of *P. hysterophorus* in the atmosphere and the different types of allergies caused by them. It is planned to undertake the abovementioned work in the second phase of our research project.

We are thankful to the CSIR, New Delhi, for the award of a Senior Research Fellowship to the junior author of this paper. We are also thankful to Prof. M. Narayan, Head of the Department of Botany, Central College, Bangalore University, Bangalore, for providing facilities to work out the present research project.

## LETTERS TO THE EDITOR

## INFRARED AND ULTRAVIOLET SPECTRA OF DI-SUBSTITUTED TOLUENES (5, 2-, 6, 3- AND 2, 4- CHLORO-FLUOROTOLUENES)

ALTHOUGH the infrared and ultraviolet absorption spectra of toluenes, mono substituted toluenes<sup>1</sup> and di-substituted toluenes<sup>2-6</sup> were investigated, fluorinated di-substituted toluenes still require a systematic study. With this in view the study of the spectra of the above-mentioned molecules has been carried out. The present communication reports the results of preliminary investigations of infrared spectra of 5, 2- and 2, 4-Chloro-fluorotoluenes and ultra-violet spectra of 5, 2- and 6, 3-Chloro-fluorotoluenes (hereafter referred to as 5, 2-CFT, 2, 4-CFT and 5, 3-CFT).

The infrared spectra were obtained on a Perkin Elmer 521 grating spectrophotometer. The ultra-violet absorption spectra were photographed with cell lengths of 50 and 70 cm on a Hilger medium quartz spectrograph. The temperature of the absorbing vapour was varied from 5° to 60° C. The time of exposure varied from 10 to 90 minutes. The chemicals were obtained from M/s. Fluka, AG, Switzerland.

All the three molecules belong to the  $C_s$  point group. The 39 fundamental vibrations of each molecule will divide into 27  $a'$  and 12  $a''$  vibrations. The transitions involved in the spectrum of each molecule would then be  $A' - A'$ , which is allowed and corresponds to  $B_{2u} + A_{1g}$  of benzene. Consequently the most intense band would be the (0, 0) band.

The most intense band at  $36136\text{ cm}^{-1}$  ( $2766.5\text{ \AA}$ ) in 5, 2-CFT and at  $36326\text{ cm}^{-1}$  ( $2752.0\text{ \AA}$ ) in 6, 3-CFT lying in the longer wavelength region of the spectra and which are observed even at lower temperatures, have been taken as the (0, 0) bands of the respective systems. In the absence of the Raman data and lack of details of the infrared band contours, the present assignments are tentative. However, a comparison with the data of related molecules shows that the assignments are in all probability correct. In order to support the vibrational assignments of 2, 5-CFT and 4, 2-CFT the corresponding frequencies of 2, 5-Di-chlorotoluene, as reported by Mehrotra<sup>3</sup> are mentioned in Table I.

The ultra-violet spectra of 5, 2-CFT and 6, 3-CFT have been analysed in terms of the following ground and excited states fundamental frequencies.

TABLE I

### Rb-Sr RADIOMETRIC STUDIES FOR THE DALHOUSIE AND ROHTANG AREAS, HIMACHAL PRADESH

ONLY scanty work has been done so far, in the field of isotopic and geochronological studies for the Himalayas, by use of Rb-Sr technique. As an example, whole-rock Rb-Sr data are available<sup>1,3</sup> for only five samples from the vast Himalayan terrain in comparison to thousands of samples from the Alps. This note describes a part of the reconnaissance type of Rb-Sr whole-rock dating which has been undertaken at Chandigarh for the granitic and gneissic rocks of N-W Himalayas.

The geochemical procedures which are being used are similar to those described by Jager<sup>3</sup>. The equipment includes a Nier-type of mass spectrometer with 90-degree 25-cm-radius magnetic analyser, equipped with a thermal ionisation source, which was fabricated and provided to us at Chandigarh by the Bhabha Atomic Research Centre, Bombay. Rb<sup>87</sup> and Sr<sup>86</sup> spikes, obtained from the Oak Ridge Laboratory of U.S. Atomic Energy Commission, have been employed.

This note describes the analyses of two whole-rock samples and one biotite sample. Results are given in Table I.

Sample PHS/22 is well enriched in radiogenic strontium. The isochron-age is, therefore, estimated to be only slightly lower than the apparent age. The granitic sample PHS/17 from the same outcrop, but from a different location, gave an apparent age<sup>2</sup> of  $456 \pm 50$  million years. From the analyses of these two samples, one can tentatively conclude that the Dalhousie granitic outcrop consists of rocks of at least two ages of emplacement, viz., about  $350 \pm 50$  m.y. and about  $450 \pm 50$  m.y. One can further conclude that the minimum age of sedimentation of the surrounding rocks into which the Dalhousie granite appears to be intruding is about  $450 \pm 50$  m.y.

Results for the biotite clearly show the re-setting of the clock during Himalayan metamorphism, which indicates that the temperature rose to more than 300°C during this period. The true age of metamorphism, however, is expected to be quite a bit lower than the apparent age of the biotite, since the initial value of Sr<sup>87</sup>/Sr<sup>86</sup> after rehomogenisation of strontium during the tertiary period is expected to be much larger than the value of 0.709, that was assumed for calculating apparent ages. It will be useful to determine the true age of biotites in this region by use of whole-rock-biotite isochrons, as has been done for the Mandi granite<sup>1</sup>.

The sample MR/7 was collected on the south-side, but almost near the top of Rohtang pass. Since it is not well enriched in radiogenic strontium, its isochron age might turn out to be considerably smaller than the apparent age. The possibility that its true age is same as that of the Mandi granite cannot be ruled out.

As pointed out earlier<sup>2</sup>, the K-Ar mineral ages for this polymetamorphic region can provide a misleading picture, unless interpreted very carefully and cautiously. A comparison between Rb-Sr data and K-Ar data for this region is not considered fruitful at present, since the published data is rather sparse and inadequate for this comparison.

TABLE I

| Sample No. | Rock-type                         | Location (Longitude/Latitude)          | Rb <sup>87</sup> in ppm | Common Sr in ppm | Sr <sup>87</sup> /Sr <sup>86</sup> | Apparent age   |
|------------|-----------------------------------|--|-------------------------|------------------|------------------------------------|----------------|
| PHS/22     | Pegmatite                         | (76° 0'; 32° 32') near Dalhousie town) | 145.5                   | 16.0             | 1.191 ± 0.03                       | 350 ± 50 m.y.  |
| MR/7       | Gneiss                            | (77° 10'; 32° 17') near Rohtang pass   | 61.8                    | 62.0             | 0.80 ± 0.02                        | 612 ± 100 m.y. |
| ID/3       | Biotite, separated from a granite | (76° 01'; 32° 33') near Kala Topc      | 850                     | 14.6             | 1.24 ± 0.03                        | 61 ± 10 m.y.   |

Constants used; Decay constant =  $1.47 \times 10^{-11}$ /year; Rb<sup>86</sup>/Rb<sup>87</sup> = 2.591, Sr<sup>88</sup>/Sr<sup>86</sup> = 8.375 and (Sr<sup>37</sup>/Sr<sup>86</sup>)<sub>i</sub> = 0.709.

showed that solutions of  $\text{CuL}_2$  in  $\text{CCl}_4$  are most susceptible to photolysis and those in benzene least susceptible, (the other usual extractants falling between these two limits), these two solvents were chosen for a detailed study.

#### Studies in Diffused Day-light

Known volumes of these solutions were taken in clear-glass stoppered bottles and were exposed to diffused day-light for different periods. Measured aliquots were removed at definite time intervals and their absorbance was determined at 435 nm. ( $\text{CuL}_2$  has a characteristic absorption peak at 435 nm due to a ligand-to-metal charge transfer band.) It was found that  $\text{CCl}_4$  solutions deteriorated fast, whereas benzene solutions appeared to be much stabler. For instance, after a 4 hour exposure to diffused day-light, the absorbance of a typical solution fell from an initial value of 0.490 to 0.340 in  $\text{CCl}_4$  medium, while in a benzene medium, it dropped from 0.490 only to 0.475.

#### Studies Using a Mercury Arc Lamp

A low pressure mercury arc lamp (Hanovia, 4 Watts, 220 volts) and a water-cooled quartz photochemical cell with an inner thimble (capacity 1 litre) were used. Standard  $\text{CuL}_2$  solutions were irradiated at two temperatures,  $30^\circ \pm 0.1$  and  $36^\circ \pm 0.1$ . The results indicated that temperature variations, as above, have practically no effect on the decomposition rate. The results of a typical study at  $30^\circ$  are given in Table I.

TABLE I

| 5             | 1.038                           | 1.970                    |
| 6             | 0.859                           | 1.960                    |
| 8             | 0.830                           | 1.910                    |
| 12            | 0.650                           | 1.840                    |
| 16            | 0.286                           | 1.820                    |
| 20            | 0.120                           | 1.770                    |
| 24            | 0.096                           | 1.665                    |

$\text{CCl}_4$ :  $k = 3.57 \times 10^{-5} \text{ sec}^{-1}$ ;  $\phi = 0.081$ ;  $t_{1/2} = 5.4$  hours. Benzene:  $k = 2.99 \times 10^{-6} \text{ sec}^{-1}$ ;  $\phi = 0.0073$ ;  $t_{1/2} = 64.4$  hours.

The progress of the substrate disappearance was followed by withdrawing small measured aliquots (2 ml) at definite time intervals, diluting to 10 ml and determining the absorbance values ( $A$ ) at 435 nm. Since the volume of the aliquot removed (2 ml) is very small in comparison with the volume of the system (1000 ml), the volume effect is ignored in the present study. A plot of  $\log (A_0/A_t)$  against time ( $t$ ) was found to be a straight line both in  $\text{CCl}_4$  and in benzene, where  $A_0$  and  $A_t$  denote absorbance at  $t = 0$  and  $t = t$ . This implies conformity with the first order kinetics. The rate constant for substrate disappearance ( $k$ ) was found to be  $3.57 \times 10^{-5} \text{ sec}^{-1}$  in  $\text{CCl}_4$  and  $2.99 \times 10^{-6} \text{ sec}^{-1}$  in benzene. The values for the time of half change are:  $t_{1/2} = 5.4 \text{ hr}$  in  $\text{CCl}_4$  and  $t_{1/2} = 64.4 \text{ hr}$  in benzene. An increase of temperature from  $30^\circ$  to  $36^\circ$  did not significantly affect the value of  $k$ . A preliminary determination of the average quantum efficiency of the decomposition gave values of  $\phi = 0.081$  in  $\text{CCl}_4$  and  $\phi = 0.0073$  in benzene.

It was observed that a solid residue was thrown down in the  $\text{CCl}_4$  medium during the course of the decomposition. This is analysed for  $\text{Cu}^{2+}$ ,  $\text{Cl}^-$  and elemental sulphur. The decomposition reaction thus appears to be complicated, as is the case with several photolytic reactions of co-ordination complexes<sup>1</sup>.

From these studies, it is clear that benzene is a better solvent than  $\text{CCl}_4$  for the spectrophotometric determination of copper.

We are grateful to Council of Scientific and Industrial Research for the award of a Junior Fellowship to one of us (K. K. M. Y.).

#### MESOMORPHIC PROPERTIES OF SOME BIPHENYL BENZOATES

SEVERAL biphenyl esters exhibit mesomorphic properties<sup>1,2</sup>. As a part of our programme of study of the structure and properties of liquid crystals, we have synthesized a homologous series of ten biphenyl-4-*p-n*-alkoxybenzoates starting from *p-n*-

alkoxybenzoic acids through their acid chlorides. The transition temperatures and elemental analyses are given in Tables I and II respectively.

TABLE I

Transition temperatures of biphenyl 4-*p*-*n*-alkoxy benzoates

| Compound number | R <sup>a</sup>                  | Transition temperatures °C | Δ T °C nematic range |
|-----------------|---------------------------------|----------------------------|----------------------|

The first five members of the series exhibit a monotropic nematic mesophase. The hexyl, heptyl, and octyl derivatives are enantiotropic nematic. The smectic mesophase appears at the decyl derivative as a monotropic phase. The plot of the transition temperatures *versus* the number of carbon atoms in the alkyl chain is given in Fig. 1, and shows the usual odd-even effect. The thermal stability of the nematic phase decreases with increasing carbon chain length. It is interesting to note that there is alternation in the crystal to isotropic transition temperatures of the first five members of the series. This alternation is attributed to a similarity in crystal structure, as evidenced from the X-ray study<sup>3</sup> of the higher homologues of *p*-*n*-alkoxybenzoic acids. These esters are thermally

less stable than the corresponding Schiff's bases reported by Gray *et al.*<sup>4</sup>

The transition temperatures were determined in open capillary tubes using a polarizing microscope (Franz Kustner Nacht KG, Dresden, Model HMK 70/3171) in conjunction with a heated stage. Infrared spectra were recorded (nujol mull) on a Perkin-Elmer spectrophotometer, Model 700 and NMR spectra were recorded on a Varian T-60 spectrometer, in CDCl<sub>3</sub> using tetramethylsilane as internal standard. The *p*-*n*-alkoxybenzoic acids were prepared according to the method of Lauer *et al.*<sup>5</sup> A typical procedure for the preparation of the ester is given below.

**Biphenyl-4-*p*-*n*-butoxy benzoate.**—*p*-*n*-Butoxybenzoic acid (3.88 g) was refluxed for 3 hours with thionyl chloride (12 ml) using a drop of pyridine. Excess of thionyl chloride was removed under reduced pressure. 4-Hydroxy biphenyl (3.4 g) in dry pyridine (60 ml) was added in one lot to the crude acid chloride, the mixture stirred for 3 hours at room temperature and left overnight. The reaction mixture was poured onto a stirred mixture of concentrated hydrochloric acid and crushed ice, when the ester precipitated out. It was filtered, washed with 10% sodium hydroxide solution, water and dried. Yield, 6.55 g.

The crude ester was chromatographed on neutral alumina (NCl, Poona, Brockmann activity 1) and was eluted with benzene. Removal of the solvent from the eluate afforded a white material, which was crystallized from benzene-light petroleum, m.p. 158–159° C.

$\nu_{\text{max}}$  1720, 1605, 1580, 1510, 1170, 980 and 760 cm<sup>-1</sup>.  $\delta$ , 1.0 (s, 3 H, -CH<sub>3</sub>); 1.2–2.0 (m, 4 H); 4.18 (t, 2 H, -OCH<sub>2</sub>); 7.0 (d, J=8 Hz, 2 H); 7.2, 7.6 (m, 9 H); 8.2 (d, J=8 Hz, 2 H).

#### A NEW VOLUMETRIC METHOD FOR THE DETERMINATION OF COPPER

We have developed a simple and quick method of determining copper which is based on the reduction of cupric salts with stannous chloride, removal of the excess of the stannous chloride by reaction with mercuric chloride and then oxidising the cuprous salt back to cupric salt with ferric sulphate which results in the production of an equivalent quantity of ferrous sulphate which is then titrated against a standard solution of potassium dichromate. The method is thus very similar to the well-known stannous chloride reduction method of the determination of iron, the major difference being that an inert atmosphere has to be maintained during the time of the removal of the excess stannous chloride with mercuric chloride and till the addition of the ferric sulphate, to prevent the oxidation of the cuprous salt by air which is very much faster than the oxidation of ferrous salts.

Very good results have been obtained by following the procedure described below.

To 10 ml of a solution containing between 0.0100 to 0.1000 g. of copper taken in 250 ml conical flask add 10 ml concentrated hydrochloric acid, mix well and then add stannous chloride solution (15 gram  $\text{SnCl}_2 \cdot 2\text{H}_2\text{O}$  dissolved in 100 ml 6 N HCl) drop by drop till the solution becomes colourless and 2 or 3 drops in excess. Add 1 to 1.5 g sodium bicarbonate followed immediately by 5 ml of a saturated solution of mercuric chloride. Close the flask with an air-tight stopper as soon as the evolution of carbon dioxide stops.

Shake gently and wait for 5 minutes for the oxidation of the excess  $\text{SnCl}_2$  by  $\text{HgCl}_2$  to go to completion. Remove the stopper and immediately add about 0.5 g sodium bicarbonate followed at once by 20 ml of an approximately N 10 ferric sulphate solution. No air should enter the flask till after the addition of the ferric sulphate solution. Shake and add 3 ml of phosphoric acid and 3 to 4 drops of 0.3% barium diphenylamine sulphonate indicator solution, dilute to 150 ml and titrate against standard potassium dichromate solution (N 20 or N 10). Each ml of N 10 potassium dichromate is equivalent to 0.006354 g of copper.

Some of the typical results obtained are given in Table I.

TABLE I

| Sl. No. | Copper taken (in grams) | Copper found (in grams) | % error |
|---------|-------------------------|-------------------------|---------|
| 1       | 0.0944                  | 0.0937                  | -0.7    |
| 2       | 0.0629                  | 0.0623                  | -1.0    |
| 3       | 0.0472                  | 0.0470                  | -0.2    |
| 4       | 0.0315                  | 0.0318                  | +1.0    |
| 5       | 0.0252                  | 0.0246                  | -2.5    |
| 6       | 0.0189                  | 0.0183                  | -3.0    |
| 7       | 0.0157                  | 0.0152                  | -3.0    |

The accuracy of the method depends on the efficiency with which air is excluded from the flask during the crucial stages as indicated above.

Only the substances which interfere in the determination of iron by the stannous chloride reduction method (Au, Pt, V, MO, W, Sb, As) interfere in this method of copper determination, besides iron. If interfering substances are present a preliminary separation of copper from them will have to be made in accordance with the classical procedures.

#### EFFECT OF PROTONATION ON THE RESTRICTED ROTATION ABOUT THE EXOCYCLIC C-N BOND OF NUCLEIC ACID BASES

THE stereochemistry and electronic structure of nucleic acid bases have been subjected to intense investigations in the literature<sup>1,2</sup>. The exocyclic C-N bond in these nucleic acid bases possess considerable double bond character<sup>3</sup>. Molecular orbital calculations have been successfully employed to estimate

the barrier heights to rotation about the C-N bond in these derivatives<sup>2</sup>. Although there are studies in the literature on the experimental determination of the structures of the protonated nucleic acid bases, molecular orbital calculations have not been carried out to understand the observed properties. Thus, it is known that adenine is protonated at the N<sub>1</sub> position in the monoprotonated adenine derivatives such as adenine hydrochloride<sup>3</sup>, 5'-adenosine mono-

calculated as a function of the angle of rotation ( $\omega$ ) around the exocyclic C-N bond, the barrier height being the difference in energies between planar conformation ( $\omega = 0^\circ$  or  $180^\circ$ ) and the transition state ( $\omega = 90^\circ$ ). All calculations were carried out with an IBM 7044/1401 computer.

Our results of the CNDO/2 calculations on the protonation of N<sub>1</sub>-methylcytosine, N<sub>9</sub>-methyladenine and guanine are given in Table I. It is known from

<sup>a</sup> E<sub>T</sub> stands for total energy and E<sub>a</sub>, for barrier height. Only those atoms showing maximum gain or loss of charge have been tabulated.

phosphate<sup>5</sup>, 3'-adenosine monophosphate<sup>6</sup>, adenosine-2'-uridine-5'-phosphate<sup>7</sup>, etc. The only doubly protonated adenine derivative studied has been adenine dihydrobromide which is protonated at N<sub>1</sub> and N<sub>7</sub> positions<sup>8</sup>. Guanine has been reported to be protonated at N<sub>7</sub> position<sup>9</sup>, whereas the site of protonation is N<sub>3</sub> in the case of the cytosine derivative, 3'-deoxycytidinemonophosphate<sup>10</sup>. It was, therefore, considered interesting to carry out a molecular orbital study employing the CNDO/2 method<sup>11</sup> on some of the protonated nucleic acid bases with the primary purpose of evaluating the barrier heights to rotation about the exocyclic C-N bond in these derivatives and to compare them with those reported in the literature for the neutral bases.

The details of the CNDO/2 method employed in our calculations have been described elsewhere<sup>12</sup>. The structural parameters were taken from the literature<sup>8-10</sup>. The energy of the molecule concerned was

the experimentally observed bond distances<sup>11</sup> that the contribution of structure IB to the overall resonance of the cytosine cation is much greater than the contribution of structure IIB to the overall resonance of the neutral cytosine. Accordingly, the barrier heights, E<sub>a</sub>, about the exocyclic C-N bond in all these derivatives increase after protonation, an observation similar to that in secondary amides<sup>12</sup>. Also, the increase in barrier height is greater in N<sub>3</sub>-protonated, N<sub>1</sub>-methylcytosine than in other derivatives. The atoms showing large difference in charge densities on protonation are C<sub>6</sub>, N<sub>1</sub>, N<sub>7</sub> and N<sub>10</sub> in N<sub>9</sub>-methyladenine, C<sub>4</sub>, N<sub>7</sub>, N<sub>10</sub> and O<sub>6</sub> in guanine and C<sub>2</sub>, C<sub>4</sub>, N<sub>3</sub>, N<sub>4</sub> and O<sub>2</sub> in cytosine. These changes in charge densities in the protonated derivatives reflect the differences observed in the structural parameters in these compounds. The barrier heights and charge densities reported here are of significance

as experimental investigations on these systems are not available.

The author is thankful to Professor C. N. R. Rao, for suggesting the problem and guidance and to the National Institutes of Health (01-078-1) for financial support.

## ABNORMAL CLAISEN REARRANGEMENT OF 4-PRENYLOXYCOUMARIN

4-PRENYLOXYCOUMARIN (I), was obtained in 7% yield when 4-hydroxycoumarin was heated with 1-chloro-3-methyl-2-butene and potassium carbonate in acetone. The reaction was catalysed by a small amount of potassium iodide. (I), on heating in dimethylaniline, gave a 2,3-dihydro-4-oxo-4 H-2,2,3-trimethyl furo (3,2-c) benzopyran (II) as the only isolatable product. The structure of (II) is confirmed by its NMR spectrum ( $\text{CDCl}_3$ );  $\delta$  1.35, doublet,  $J = 7$  Hz, 3 H at position 3; 1.50, 1.55, two singlets, 6 H of two  $-\text{CH}_3$  at position 2; 3.25, quartet,  $J = 7$  Hz, 1 H at position 3; 7.5, multiplet, 4 H aromatic. If (II) were a normal Claisen migration product, it would have structure (III a), in which case the characteristic quartet of 1 H at position 2 would have appeared in the downfield in the NMR spectrum. Similar type of abnormal Claisen migration has been observed by Jain and Jain<sup>1</sup> during their studies on the Claisen migration of prenyloxy derivatives of phenylbenzylketones.

In view of the above abnormal Claisen migration of 4-prenyloxycoumarin, the Claisen migration of 4-allyloxycoumarin was reinvestigated. 4-Allyloxycoumarin on heating in dimethylaniline gave the normal 2,3-dihydro-4-oxo-4 H-2-methyl furo (3,2-c) benzopyran (III b)<sup>2</sup>. The structure of (III b) is

- (a)  $R = \text{CH}_3$   
(b)  $R = \text{H}$

- (a)  $R = \text{Prenyl}$   
(b)  $R = \text{Allyl}$

confirmed by its NMR spectrum ( $\text{CCl}_4$ );  $\delta$  1.55, doublet,  $J = 7$  Hz, 3 H at position 2; 2.95, multiplet, 2 H at position 3; 5.2, multiplet, 1 H at position 2; 7.25, multiplet, 4 H aromatic. In this

case, the characteristic signal of 1H at position 2 appears downfield. In both the cases, the intermediate migration products, 4-hydroxy-3-prenylcoumarin (IV a) and 4-hydroxy-3-allylcoumarin (IV b) formed are simultaneously cyclized to form the furan ring structure: but however, in the former case the migration is abnormal while in the latter it is normal.

#### EXPERIMENTAL

**4-Prenyloxy coumarin (I).**—A solution of 4-hydroxy-coumarin (1.5 g), potassium iodide (1 g), anhydrous potassium carbonate (3 g) and 1-chloro-3-methyl-2-butene (1 g) in acetone (50 ml) was refluxed for 6 hr. Acetone was distilled off and water was added to the residue, and the whole solution was extracted with ether. Removal of ether gave a solid, which crystallised from petroleum ether, m.p. 98°. Yield 0.2 g (Found: C, 73.26; H, 5.95;  $C_{14}H_{14}O_3$  requires C, 73.04; H, 6.08%).

**2,3-Dihydro-4-oxo-4H-2,3-trimethyl furo (3,2-c) benzopyran (II).**—A solution of 4-prenyloxy coumarin (I) (0.5 g) was refluxed with dimethylaniline (3 ml) for 6 hr the mixture was cooled and added to ice-cold hydrochloric acid. It was extracted with ether and the ether layer was washed with 1% sodium hydroxide solution ( $3 \times 20$  ml). The solid obtained after the evaporation of the ether crystallised from petroleum ether, m.p. 85–86°. Yield 0.4 g. (Found: C, 73.02; H, 6.16;  $C_{14}H_{14}O_3$  requires C, 73.04; H, 6.08%).

Thanks are due to Shri S. G. Amin, Steven's Institute of Technology, Hoboken, U.S.A. and Dr. Sukh Dev, Director, Malti-Chem. Research Centre, Nandesari, District Baroda for NMR spectra. Thanks are due to Prof. Sethna for keen interest in the work and to Dr. S. S. Lele, for microanalysis of the samples.

#### SOME OBSERVATIONS ON THE NENCKI REACTION WITH RESORCINOL DERIVATIVES

In the course of our work on the synthesis of aromatic ketones, we happened to study the Nencki reaction on some resorcinol derivatives, when some interesting observations were made which are reported here.

Both *p*- and *m*-resorcylic acids on heating with glacial acetic acid in the presence of anhydrous zinc chloride (2 mol.) for 5–7 minutes underwent decarboxylation and gave resacetophenone in 55 and 50% yields respectively. On the other hand, *o*-resorcylic acid failed to react with acetic acid even in the presence of a large excess of zinc chloride (10 moles), anhydrous aluminium chloride or  $BF_3$  and was recovered unchanged in almost quantitative yields. *p*-Resorcylaldehyde under the conditions of the Nencki reaction afforded a brownish dark solid from which no definite substance could be isolated except the original aldehyde in traces (identified as 2, 4-DNP). Resacetophenone was recovered unchanged in the Nencki reaction with acetic acid under different conditions.

However, both 2-methyl- and 4-ethyl-resorcinols reacted with acetic acid and  $ZnCl_2$  to yield the corresponding ketones, namely, 2, 4-dihydroxy-3-methylacetophenone, m.p. 156° (prepared previously by Hoesch reaction<sup>1</sup>) (2, 4-DNP m.p. above 300°) and (2, 4-dihydroxy-5-ethylacetophenone<sup>2</sup>, m.p. 116°) (2, 4-DNP m.p. 236°) in about 70% yields.

It therefore appears that electron withdrawing groups hinder the reaction whereas electron repelling groups favour it. An exception is orcinol which does not undergo the Nencki reaction.

Also, decarboxylation during the Nencki was not observed in the case of the *o*- and *m*-cresotic acids which were recovered unchanged.

#### CHEMICAL INVESTIGATION OF CRATAEVA NURVALA, A SEARCH FOR THE ANTI-INFLAMMATORY PRINCIPLE

*Crataeva nurvala* Buch.-Ham. and *C. religiosa* (Capparidaceae) form the source of *Varuna* which finds several uses in Ayurvedic medicine<sup>1,2</sup>. The major constituents of both are lupeol and sitosterol<sup>3,4</sup>. The encouraging anti-inflammatory, anti-arthritis and corticosteroid-like activity<sup>5</sup> of the petrol extract of *C. nurvala* prompted us to reinvestigate the chemical constituents of this extract.

Dried and pulverised root bark of *C. nurvala* (2.5 kg) extracted with petrol (60–80°) furnished a light yellow residue which, on repeated crystallisations from benzene, furnished colourless needles (yield, 0.06%) of  $C_{30}H_{50}O$  ( $M^+$ , 426), m.p.

209–211°, which were found to be identical with lupeol by direct comparison (mixed m.p., superimposable I.R. and CO-TLC). The mother liquor of lupeol on chromatography over Brockmann alumina and elution with pet. ether furnished a solid which crystallised from acetone to give needle-shaped crystals, m.p. 168–169° (yield 0.34%). The compound gave positive test for triterpene with Liebermann-Burchard reagent. It analysed for  $C_{30}H_{48}O$  (M<sub>r</sub>: 424) and showed a carbonyl absorption at 1698  $cm^{-1}$ . The mass spectrum of this compound, besides the molecular ion peak at m/e 424, showed important ion peaks at m/e 409 (M-Me), 381, 218, 205, 189, which indicated its identity with lupen-3-one<sup>6</sup>. This was finally confirmed by its reduction with sodium borohydride to lupeol and by its direct comparison with lupen-3-one obtained by Jones oxidation of lupeol.

Benzene-chloroform and ethyl acetate eluates furnished sitosterol, m.p. 135–136°, and a solid, m.p. 71–72°, which on the basis of IR, NMR and Mass spectral studies and reaction with diazomethane was identified as stearic acid,  $C_{18}H_{36}O_2$ , admixed with  $C_{20}$ ,  $C_{22}$ ,  $C_{24}$  and  $C_{26}$  fatty acids.

Pharmacological investigation<sup>7</sup> with different fractions of *C. nurvala* revealed that the anti-inflammatory property of the total petrol extract is neither due to lupeol nor lupen-3-one, but due to an oily liquid, the least polar fraction of the petrol extract. This oil on careful chromatography over air-dried silica gel G plate showed four overlapping spots (solvent system, P.E. :  $C_6H_6$ , 4 : 1) indicating the complexity of the mixture. Attempts for resolution of this mixture by column or preparative TLC were unsuccessful. The mixture showed positive L-B test for sterol and its I.R. spectrum showed an ester carbonyl band at 1742  $cm^{-1}$ . In accordance with this observation, the oil on alkali hydrolysis furnished an acid ( $\nu_{max}$  1715  $cm^{-1}$ ) and an alcohol ( $\nu_{max}$  3400  $cm^{-1}$ ) both of which were found to be mixtures by TLC studies. The low yield and the complexity of this mixture necessitate combined GLC-Mass spectral studies. Work in this direction is in progress.

#### LIGNANS FROM THE STEM BARK OF *ZANTHOXYLUM ACANTHAPODIUM* DC.

*Zanthoxylum acanthopodium* DC (family Rutaceae) is valued as a medicinal plant<sup>1</sup>. Two flavonoids, tambulin<sup>2</sup> and tambuletin<sup>2,3</sup> were isolated from the fruits. Kumar *et al.*<sup>4</sup>, reported the presence of linalool, dipentene, phellandrene and citral in the oil of crushed seeds. This report deals with the isolation and identification of the lignans of the stem bark.

The powdered stem bark was extracted with petroleum ether and the extract on evaporation left a yellowish brown residue. The residue turned partly crystalline after a week. The crystalline solid was separated from the residue by dissolving it with benzene-petroleum ether and filtering. The filtrate was concentrated *in vacuo*, chromatographed over silica gel and eluted with solvents of increasing polarity. The fractions were purified by repeated crystallisations until the compounds were homogeneous in TLC. Six pure neutral lignans were obtained of which three, m.p. 174–77°, 193–95° and 119–20°, were obtained in very small yields. The other three were marked A, B and C.

Compound A (I) obtained from benzene-chloroform (9 : 1) eluate, crystallized as white needles from petroleum etherbenzene, m.p. 123–24°,  $[\alpha]_D^{25} + 64.8^\circ$  (CHCl<sub>3</sub>),  $\lambda_{max}^{E:OH}$  237 and 287 nm,  $\nu_{max}^{CHCl_3}$  2870, 1615, 1490, 1345, 1100, 1060, 1025, 940 and 860  $cm^{-1}$ . It gave positive Labat test (green colour) for methylenedioxy group and analysed for  $C_{20}H_{18}O_4$ . From these properties it was identified as (–)-sesamin and the identity was confirmed by comparison with an authentic sample (mmp and Co-TLC).

Compound B (II) was obtained from benzene-chloroform (3:1) and (1:1) eluates. It crystallised as white plates from petroleum ether-benzene, m.p. 159–41°.  $\lambda_{\text{max}}^{\text{EtOH}}$  236 and 285 nm.  $\nu_{\text{max}}^{\text{KBr}}$  1610, 1590, 1230, 1025, 930, 810 and 720  $\text{cm}^{-1}$ . It analysed for  $\text{C}_{21}\text{H}_{22}\text{O}_5$  ( $M^+$  370) with two methoxys.

I, Ia

II, IIa

- I Ar = 3,4-methylenedioxy phenyl .. sesamin  
 Ia Ar = 3,4-dimethoxy phenyl .. eudesmin  
 II Ar = 3,4-dimethoxyphenyl  
 Ar' = 3,4-methylenedioxyphenyl } fargesin  
 IIa Ar = 3-methoxy-4-hydroxy phenyl  
 Ar' = 3,4-methylenedioxy phenyl } pluviatilol

On permanganate oxidation, it afforded a mixture of veratric acid and piperonylic acid. The presence of dimethoxyphenyl and methylenedioxy groups was also indicated in the n.m.r. spectrum (see Table I). The n.m.r. ( $\text{CDCl}_3$ ) and mass spectra showed that it is a lignan containing a 3,7-dioxabicyclo[3.3.0]octane skeleton. Two doublet signals at  $\delta$  4.8 ( $J = 5$  Hz) and  $\delta$  4.4 ( $J = 7$  Hz) suggested the presence of *cis-trans* configuration in the compound<sup>5</sup>. The striking similarity of the upfield portion of the spectrum of the compound to that of epipinoresinol dimethyl ether also suggested the presence of *cis-trans* configuration. Mass spectral pattern of the compound shows in addition to the molecular ion,  $m/e$  340 (2.5); 220 (4); 204 (9); 219 (9); 203 (23); 184 (2); 168 (2.5); 177 (45); 161 (23); 166 (25); 150 (21); 165 (40); 149 (82); 151 (34); 135 (44); 137 (5); 121 (11); 131 (17); 150 (21); 160 (4) and 178 (16). The spectral data closely agree with that of methyl pluviatilol<sup>6</sup>, m.p. 133–34°.  $[\alpha]_D^{25} - 122^\circ$  which was obtained by methylation of pluviatilol (IIa), a phenolic lignan reported to occur in *Zanthoxylum pluviatilifolium*<sup>6</sup>. Fargesin, m.p. 139°, recently reported as a new natural lignan from the flower buds of *Magnolia fargesii*<sup>7</sup> has also been assigned the same structure. The optical rotation of fargesin has not been cited, but presumably it is racemic. Thus fargesin can be considered as racemic methyl pluviatilol. The specific rotation of compound B is  $+1^\circ \pm 0.5^\circ$  ( $\text{CHCl}_3$ ), suggesting that it is chiefly racemic methyl

pluviatilol or fargesin. This is the second report of the occurrence of this lignan in nature.

TABLE I  
NMR Spectral data of compounds B & C

| Assignment of protons   | Compound B (fargesin) | Compound C (eudesmin) |
|-------------------------|-----------------------|-----------------------|
| 1 H                     | 2.85 m                | 3.08 m                |
| 5 H                     | 3.3 m                 |                       |
| 2 H                     | 4.8 d ( $J = 5$ Hz)   | 4.78 d ( $J = 4$ Hz)  |
| 6 H                     | 4.41 d ( $J = 7$ Hz)  |                       |
| 4 H                     | 3.3 m                 | 4.17–4.4 m            |
|                         | 3.6–4.02 m            |                       |
| 8 H                     | 3.06–4.02 m           | 3.8–4.0 m             |
|                         | 4.02–4.2 m            |                       |
| $\text{OCH}_3$          | 3.84 s                | 3.86, 3.88            |
| $\text{O}_2\text{CH}_2$ | 5.95 s                | ..                    |
| Aromatic                | 6.78–6.85 m           | 6.85–6.9 m            |

Compound C (Ia), obtained from chloroform-methanol (9:1) eluate, crystallised as white needles from petroleum ether-benzene, m.p. 91–92°.  $[\alpha]_D^{25} 0^\circ$  ( $\text{CHCl}_3$ ).  $\lambda_{\text{max}}^{\text{EtOH}}$  234 and 284 nm,  $\nu_{\text{max}}^{\text{KBr}}$  1590, 1520, 1260, 1240, 1025 and 835  $\text{cm}^{-1}$ . The molecular formula ( $\text{C}_{22}\text{H}_{24}\text{O}_5$ ) was assigned from elemental analysis and mass spectrum ( $M^+$  386) [ $m/e$  386 (100), 356 (3), 220 (11), 290 (26), 194 (18), 177 (89), 166 (48), 165 (96), 151 (63) and 134 (4.5)]. On  $\text{KMnO}_4$  oxidation it gave only veratric acid. This showed the presence of dimethoxyphenyl group in the compound. It was confirmed from the n.m.r. spectrum (Table I). A doublet integrating for 2 protons at  $\delta$  4.78 ( $J = 4$  Hz) suggested the presence of diequatorial of *trans-trans* configuration in the compound. These results are in accord with the results of Weinges<sup>8</sup> who reported that a doublet at  $\delta$  4.8 ( $J = 4$  Hz) in sesamin was an indication of *trans-trans* configuration. The spectral data of the compound is in agreement with pinoresinol dimethyl ether (eudesmin). The m.p. and optical rotation indicate that compound C is ( $\pm$ )-pinoresinol dimethyl ether.

The author's thanks are due to Prof. Mrs. Ashima Chatterjee, Calcutta University, for supplying a sample of sesamin for comparison, Prof. Jay Nematollahi, College of Pharmacy, University of Texas at Austin for providing spectral data and Dr. N. A. Hughes, University of Newcastle upon Tyne for determining the specific rotation of compound B on an automatic polarimeter.

### SYN-FOLIATION RECLINED FOLDS FROM EASTERN GHAT BELT ROCKS OF PALGHAT DISTRICT, KERALA STATE

Two generations of folds in different scales on foliation are commonly recognised in parts of the Eastern Ghat belt, viz., an earlier generation ( $F_1$ ) running parallel to foliation trend and a later generation ( $F_{11}$ ) of cross folds with their axial traces either perpendicular or at high angle to the former<sup>1-2</sup>.

A third generation of folds ( $F$ ) older than the two mentioned above and with which the formation of foliation is associated in time has been observed recently by the authors during field investigations.

Northwest of Alathur ( $10^\circ 39' : 76^\circ 32' 30''$ ) along the Gayathri river bed two tightly appressed reclined folds with a southerly plunge are formed by a one m thick hypersthene granulite band in biotite gneiss (Fig. 1). The granulite band pinches

off suddenly into the surrounding biotite gneiss east and west of the fold closures. As there is only minor variation in the attitude of the contact ( $S_0$ ) between the granulite band and the gneiss in fold limbs, folding is isoclinal in effect. Parallel to the E-W trending axial surfaces of these folds megascopic foliation (axial surface foliation) is observed in biotite gneiss due to planar preferential arrangement of biotite flakes. While  $S_0$  surfaces curve round the fold closures, foliation surfaces ( $S_1$ ) cut

across  $S_0$  in fold closures. This relationship clearly shows that  $S_0$  is a pre-foliation planar surface that was present in rocks at the time of  $F$  folding and  $S_1$  is a later planar surface formed by secondary metamorphic crystallisation. Further, since  $S_1$  is axial surface foliation with respect to  $F$  folds and has not been affected by  $F$  folding, both  $F$  folding and generation of  $S_1$  are broadly synchronous.  $F$  folds are therefore syn-foliation folds and the metamorphic peak as indicated by the formation of foliation ( $S_1$ ) coincides in time with  $F$  folding.

The syn- and pre-foliation deformational history of the Eastern Ghat belt metamorphic rocks of Kerala and neighbouring areas is little known. Recognition of syn-foliation folds establishes that the major metamorphic event which is synchronous with  $F$  folding must have evidently pre-dated the commonly recognised  $F_1$  and  $F_{11}$  folding episodes in these rocks.

This work forms part of a U.G.C. sponsored research project. The authors are grateful to Prof. K. K. Menon, Head of the Department of Geology, University of Kerala, for providing facilities for the present study. One of the authors (G. P. M.) is thankful to the C.S.I.R. for the award of a Junior Research Fellowship.

### BREEDING OF SILVER CARP HYPOPHthalmichthys MOLITRIX (C. AND V.) AND GRASS CARP CTENOPHARYNGODON IDELLA (VAL.) IN A BUNDH TYPE TANK IN WEST BENGAL

IN 1959 Chinese carps, i.e., silver carp, *Hypophthalmichthys molitrix* (C. & V.) and grass carp, *Ctenopharyngodon idella* (Val.) were introduced into India by the Central Inland Fisheries Research Institute, Barrackpore<sup>1</sup>. They are compatible with Indian major carps and thus their culture along with them has been tried by various workers as composite fish culture to maximise fish production in pond.<sup>2-4</sup> Because of their phenomenal growth they are in great demand for composite fish culture. But great difficulty is experienced in obtaining the desired quantity of seed of these carps for stocking as the fishes do not naturally breed in ponds. Even after getting the injections of pituitary hormone unlike Indian major carps they require stripping.

For massive fish seed production, the Indian major carps are bred in perennial as well as seasonal impoundments locally known respectively as wet and dry bundhs in certain districts of West Bengal and Madhya Pradesh<sup>2</sup>. The usual procedure prevalent now in West Bengal is to release the fish in quantity in bundhs after injecting some of them with pituitary extract. The breeding takes place within six hours of injection. An attempt was therefore made to breed silver carp and grass carp in dry bundhs at Simlapal, Bunkura District, West Bengal, during the month of July, 1974. On 7th July, 1974, one female and two males of silver carp were injected @ 9 mg/kg and 4 mg/kg body weight of the fishes respectively and put in a *hapa* fixed in a bundh so as to see the effect of the pituitary injection on the gonad of the female fish while it is in the bundh. Water was allowed to flow in and out of the bundh through the inlet and outlet. A considerable number of eggs has been found already regressed when the female was stripped the following morning. Even so, about 50,000 eggs could be fertilised and their development proceeded upto the formation of embryo after which all of them died. On 30th July 1974, four sets, two of grass carp (consisting of 2 females and 3 males) and two of silver carp (consisting of 2 females and 5 males) were used in the experiment. The female fishes were released in a ditch (10' x 12' x 1') by the side of the bundh after giving a first dose of pituitary extract injection @ 3 mg/kg body weight at 17 hours. Males did not receive any injection at that time. Second injection @ 10 mg/kg, to the females was given at 20-30 hr when males were also injected @ 7 mg/kg and then both the females and males were released in a small dry bundh measuring 50' x 20' with a sloping bottom having a water depth ranging from 6 inches to 1½ feet. One of the females of grass carp died on being released in the bundh, since it slipped from the net and got injured at the time of injection. The inlet and the outlet of the bundh were opened after the release of fish. The water was allowed to flow in from a bigger tank of about 2 hectares containing rain water. This was continued upto 03-00 hr on 31st July, 1974, when both the inlet and the outlet were closed. At about 03-30 hr some fishes were seen coming to the surface and moving around. The activity became intense at 04-00 hr but slowed down at 05-00 hr. At about 05-30 hr, a small piece of mosquito net was dragged and from deeper portion some swollen eggs were recovered. The fishes again came to surface at 06-00 hr and started moving to and fro in the bundh as if searching for food. At 06-30 hr, a pair of silver carp was seen moving together

and sometimes bending very close to each other. At the same time, the grass carp male was seen following the female and nudging the female off and on. At 06-45 hr grass carp courtship could be observed. The male was seen bending over the female and clasping it. A sound of 'chap chap' was produced by the female fish by the brisk movements of its tail. Sex play in grass carp has never been seen or reported, yet the same was clearly observed from 06-30 hr to 09-00 hr in the present experiment in the bundh. Some eggs were collected at about 11-00 hr and kept in enamel trays to watch the development of the zygote. Blastodisc had already been formed in most of the eggs by that time. The percentage of fertilization was about 50%.

The collection of eggs from the bundh was started when the embryo had already been differentiated at 15-00 hr on 31st July with mosquito net *gamcha*. A total of 3.5 lakhs of eggs were collected and kept in hatching *hapas* and earthen pits for hatching. The eggs started hatching from 19-00 hr which continued upto 23-00 hr. After the removal of eggs from the bundh the fishes were examined and it was seen that the female grass carp and one of the two silver carp females fully bred. The experiments clearly indicate that Chinese carps like Indian major carps can breed in bundh type tank and thus the bundh breeding appears to be the solution for mass breeding of these carps so as to meet the ever increasing demand of their seed.

The authors are grateful to Dr. V. G. Jhingran, Director, Central Inland Fisheries Research Institute, Barrackpore, for his keen interest in this research and also for kind encouragement, to Shri B. N. Poddar, Ex-Director of Fisheries, Government of West Bengal, for certain facilities for the work; and to Shri Nalini Ranjan Singha Babu for providing his bundh for the experiment.

# EFFECT OF SALINITY ON THE FREE AMINO ACID COMPOSITION OF THE HEMOLYMPH OF A MARINE CRAB—*OCYPODE PLATYTARSIS*

MARINE invertebrates show a decrease in tissue free amino acid levels during periods of osmotic stress in reduced salinities<sup>1,2</sup>. The changes in the tissue free amino acids result in the alteration of free amino acids content in the body fluid<sup>3</sup>. Hitherto little attempt has been made to study the possible changes of free amino acids in the hemolymph of marine crustaceans during the periods of osmotic adjustment. It was therefore considered worthwhile to investigate the changes in the free amino acid pattern of the hemolymph of supra-tidal marine crab, *Ocypode platytarsis*, by acclimating them to different salinities.

*O. platytarsis* is a euryhaline and a good osmo-regulator<sup>4</sup>. To avoid the influence of size, sex and moult stages in the free amino acids of the blood<sup>5</sup>, in the present study, intermoult male crabs of size 85–95 mm were chosen. They were acclimated by maintaining them in 25‰, 50‰, 75‰ and 100‰ sea water for about 12 days at room temperature during which period they were not fed. Crabs collected from the field with the sand were maintained in the laboratory and were used as control under starvation. The experimental animals were prechilled for 4 minutes before drawing blood<sup>6</sup>. The blood was collected in the pre-chilled centrifuge tubes and the free amino acids were separated using ethanol and chloroform employing ascending paper chromatography. The chromatograms were run with *n*-butanol, acetic acid and water (4:1:1 v/v). Besides 0.1% (wt/vol.) ninhydrin solution in acetone, the following spray reagents were employed: Isatin for proline, Pauly's reagent for histidine and tyrosine, Folin's and  $\alpha$ -nitroso  $\beta$ -naphthol for tyrosine<sup>7</sup>.  $R_f$  values were determined and compared with the standards run simultaneously under identical conditions.

The results (Table I) showed that there is a marked difference in the free amino acid pattern of body fluid of the crabs acclimated to various salinities. Normal crabs (controls) showed the presence of histidine, arginine, glycine, alanine, aspartic acid, tyrosine, valine and phenylalanine while in experimental animals, arginine and aspartic acid were absent whereas proline was present.

In addition, crabs acclimated to various salinities showed differences among them. Crabs acclimated in 100‰ sea water showed glycine and histidine to be dominant while tyrosine was in trace amount. Though lysine and aspartic acid were absent in these crabs as in normal animals, these amino acids, however, were present in crabs acclimated to lower salinities (25‰ and 50‰). On the other hand, there was no difference in the amino acid pattern

TABLE I

Free amino acid pattern of the hemolymph of the marine crab—*Ocypode platytarsis* after acclimation to various salinities

of the hemolymph of crabs acclimated to 25‰ and 50‰ sea water. In 75‰ sea water acclimated crabs, lysine was absent.

These results reveal that the changes in the pattern of free amino acids are in general agreement with the earlier reports on other marine invertebrates<sup>1-3</sup> in which the total quantity of free amino acids of the body fluid increases during acclimation at reduced salinities. This has been suggested as due to fall in the tissue free amino acid level in order to balance the osmotic stress at reduced salinities<sup>3</sup>. The present study supports the concept that there is a correlation between the habitat and the free amino acid composition of the body fluids.

# A NEW RECORD OF THE CLUPEID FISH, *ILISHA KAMPENI* (WEBER AND de BEAUFORT) FROM THE BAY OF BENGAL

*Ilisha kampeni* (Weber and de Beaufort, 1913)<sup>1</sup> was originally described as *Pellona kampeni* from Java and Borneo. Norman (1923)<sup>2</sup> recorded the species from Madras, based on a single specimen in the British Museum, but this fish has been identified as *I. megaloptera* (Swainson, 1839) by Whitehead (in litt.). Based on this fact Whitehead (1970)<sup>3</sup> equated *I. kampeni* with *I. megaloptera*. *Ilisha kampeni*, which seems to have escaped the attention of ichthyologists all these years, is now recorded for the first time from the Indian waters: Ramaiyan, Natarajan and Whitehead (in preparation) describe further specimens from Porto Novo. The anomalous Porto Novo specimens mentioned by Whitehead (1973)<sup>4</sup> are also *I. kampeni*.

**Description:** based on 95 specimens, 72–148 mm SL. Kakinada, Andhra Pradesh, 11 June 1970.

Branchiostegals 6. D 16–18, P 14–16, V 7. A 42–45, gillrakers 10–11–21–23, scutes 18–20–8–9 (total 26–28); scales in median lateral series 38–40. In percentages of SL: body depth 26.2–29.5, head length 25.8–27.6, snout length 6.9–8.7, eye diameter 6.9–8.7, pre-dorsal distance 45.2–49.2.

Body compressed, its width  $3\frac{1}{2}$  times in its depth, deepest under dorsal origin. Belly keeled, scutes beginning at isthmus, not as troncotent and prominent as in *I. megaloptera* in the post-pelvic region. Maxilla reaching to below middle of eye. No hypomaxilla. Two supramaxillae. Frontals with two prominent ridges of modified *megaloptera* pattern (see Seshagiri Rao, 1972).

Pseudobranch present, basal half covered by a thin membrane (exposed in other species). Dorsal origin a little nearer snout tip than to caudal base. Pectorals almost reaching pelvic base or failing to reach pelvic base by  $\frac{1}{2}$  eye diameter. Anal origin below 8–10 branched dorsal ray.

Swimbladder with paired post-coelomic extensions. **Colour:** Dorsal profile dark gray, upper 1.3rd of flanks light brown with greenish tinge, remainder of flanks silvery white. Posterior half of dorsal fin dark gray at finary tips. Pectorals, pelvics and anal hyaline. Margin of caudal dark.

**Identification and synonymy.**—Considerable confusion exists in the identification of species of *Ilisha*. The form of the swimbladder has recently been found to be an important diagnostic character (Talwar and Whitehead<sup>5</sup>, Seshagiri Rao<sup>6,7</sup>). However, the form of swimbladder in the types of *I. kampeni* had not hitherto been described. Having accepted that Norman's Madras specimen of *I. kampeni* was *I. megaloptera*,

and in the absence of any subsequent record of the former species from the Indian Ocean, I described a new species *I. whiteheadi* from Kakinada which differed from *I. megaloptera* in having a swimbladder with paired post-coelomic extensions (vs. single, present on right side of body only in *I. megaloptera*). Subsequent to the acceptance of the above paper, Whitehead examined Weber and de Beaufort's specimens and informed me that the types of *I. kampeni* have a swimbladder form similar to that in *I. whiteheadi*. It is now presumed that *I. whiteheadi* is a junior synonym of *I. kampeni*; the meristic and morphometric figures given here agree with those in my description of *I. whiteheadi* and with those of the types of *I. kampeni* (Table I).

TABLE I

Comparison of meristic and morphometric characters of syntype of *Pellona* (= *Ilisha*) *kampeni* from ZMA, Amsterdam with specimens from Kakinada and Porto Novo, India

| Character       | 4 syntypes of <i>Pellona kampeni</i> ZMA, 100.0–118.5 mm SL* | 95 specimens from Kakinada 72–148 mm SL | 64 specimens from Porto Novo† 68.0–134.3 mm SL |

## EFFECT OF STILBESTROL ON THE GLYCOGEN AND CHOLESTEROL CONTENT OF THE RABBIT UTERUS

NATURAL AND SYNTHETIC oestrogenic substances are one of the potent inhibitors of ovulation<sup>1</sup> as well as of implantation<sup>2</sup>. Little is known about the changes which such substances particularly synthetic non-steroidal oestrogens bring about in the biochemical make-up of the mammalian uterus. Such a study becomes more pertinent since these substances are being increasingly utilized in the clinical interception of pregnancy<sup>3</sup>. This report records the effect of stilbestrol on the glycogen and cholesterol content of the rabbit uterus at progressively increasing intervals of time after the drug administration, and forms a part of a study to evaluate the mechanism of action of postcoital antifertility substances.

Stilbestrol was administered to parous non-gravid rabbit does weighing from 2 to 2.5 kg. A total dose of 1 mg per rabbit was injected in three daily fractions contained in 0.1 ml of olive oil per day. This dose is the minimum 100% effective postcoital antifertility dose for the rabbit. Autopsies were made 24 hours, 72 hours and 144 hours after the last injection. Controls were injected with the vehicle alone. At autopsy, the reproductive tract was quickly exposed, the uterine cornu were excised and then freed from all adhering connective and fatty tissue. Preparation of tissue was done throughout in an ice-bath. Quantitative estimation of the uterine glycogen was done by the method of Montgomery<sup>4</sup> and that of cholesterol by the technique of Zak as described by Hawk<sup>10</sup>. The results were statistically analysed by "Student's" *t*-test<sup>5</sup>.

\* Highly significant ( $p < 0.001$ ).

Table I presents the glycogen and cholesterol values of the uterus of the control and stilbestrol-treated rabbits. It is well known that oestrogen stimulation results in an increase in the uterine glycogen among the rodents<sup>4</sup>. It has also been described that glycogen accumulates mainly in the muscle of the myometrium and endometrium to act as an energy source for uterine contraction<sup>5</sup>. It has been suggested that this increase in the uterine glycogen may result from a stimulation of hexokinase by oestrogenic substances<sup>6</sup>. In the rabbit uterus a similar significant increase ( $p < 0.001$ ) in the uterine glycogen content is noticed after 24 hours of stilbestrol administration; there is then a fall in the glycogen value to the control level by 72 hours of drug administration, probably because the influence of the hormone wears off by this time. However, this drop in the uterine glycogen does not stop but further declines significantly ( $p < 0.001$ ) in rabbits examined after 144 hours of treatment.

In the mouse, oestradiol dipropionate does not seem to influence the uterine cholesterol content<sup>4</sup>, while it has also been reported that oestrogen encourages the binding of labelled acetate to cholesterol in the mouse uterus<sup>1</sup>. In the rabbit, stilbestrol treatment results in a significant decline ( $p < 0.001$ ) of the cholesterol content of the uterus after 24 hours of administration. However, after 72 and 144 hours of treatment the uterine cholesterol levels are significantly elevated ( $p < 0.001$ ). Therefore, it is apparent that the uterine cholesterol content of the rabbit is labile to oestrogen. The exact role played by cholesterol in the economy of the mammalian uterus is not clearly understood, however, it may be added that oestrogen may influence the conversion of uterine cholesterol to other compounds

or may stimulate its synthesis from its acetate precursor, resulting in its decrease or increase in the rabbit uterus.

## URIC ACID SYNTHESIS DURING AESTIVATION IN *PILA GLOBOSA*

AESTIVATION in the snail, *Pila globosa*, is associated with many changes in nitrogen metabolism. Ammonia and urea are the major nitrogen excretory products in its active life<sup>1</sup> which show a decrease on 3 month aestivation<sup>2,3</sup>. Uric acid on the other hand shows a multifold increase in many tissues of the snail<sup>2,4</sup>. There was no change in the ribonucleic acid content in the hepatopancreas during aestivation<sup>5</sup>. But a significant decrease of the protein

content in the hepatopancreas, mantle and foot was observed<sup>1,6</sup>. Needham<sup>7</sup> pointed out that accumulation within a snail of less than 1 mg uric acid/gm wet weight might be a consequence of nucleic metabolism. But in aestivated snail tissue uric acid values were higher than 4 mg/gm wet weight<sup>3,4</sup> indicating an extensive synthesis of uric acid. Bricteux-Gregoire and Florkin<sup>8</sup> showed that uric acid in gastropods is synthesized from simple precursors, viz., carbon dioxide, acetate, formate, glycine, aspartic acid, glutamic acid. Hence it will be more pertinent if some enzymes specially those concerning with the synthesis of uric acid are studied. In the present report xanthine oxidase which catalyses the conversion of xanthine or hypoxanthine to uric acid was studied since it would give precise information about the increased uric acid metabolism during aestivation in *Pila globosa*.

Xanthine oxidase (EC 1.2.3.2) activity in the tissues was estimated by the dye reduction method of Nachlas *et al.*<sup>9</sup> using 2-(*p*-iodophenyl)-3-(*p*-nitrophenyl)-5-phenyl tetrazolium chloride (INT) as the terminal electron acceptor.

It is found that xanthine oxidase activity is not limited to hepatopancreas alone but is also found in mantle, foot, intestine and heart suggesting that all these tissues potentially oxidise hypoxanthine to uric acid. However, the hepatopancreas had the highest level of activity of the enzyme and next being mantle. Thus, the hepatopancreas is the major centre of uric acid synthesis while mantle is next in the synthetic activity.

On aestivation, the xanthine oxidase activity was found to increase by 85% in hepatopancreas, 60% in mantle, 95% in foot, 52% in intestine and 53% in heart. Though per cent increase of the enzyme activity appears to be high in foot, the total enzyme activity level is high in the hepatopancreas and mantle than the other tissues of aestivated animals suggesting that the major sites of uric acid synthesis remain unaltered. The synthesis of uric

acid is elevated in the foot, intestine and heart indicating the tendency towards increased input of nitrogenous wastes. The other tissues, viz., stomach, nephridium, ctenidium, penis, testis had no detectable enzyme activity either in active or in aestivated snail. The reported accumulation of uric acid in those tissues may be due to the transport of uric acid biosynthesised in the hepatopancreas and mantle. Uric acid levels increase in the body fluid of 45 days and 90 days aestivated snails<sup>10</sup> suggesting that transport of uric acid is mediated by this medium. Similar mobilization of uric acid has been reported in the prosobranch, *Thais*<sup>11</sup>. The aestivating *Pila globosa* might have found these organs, viz., stomach, penis, testis, ctenidium as convenient sites for accumulation of uric acid since their natural functions cease to operate.

Though the uric acid synthesis was found in the active snail tissues, uric acid could not be the principal nitrogenous end product since ammonia and urea were found to be the major excretory products in the active snail<sup>12</sup>. Since the presence of an active urea cycle is much debated in gastropods<sup>11,12</sup>, urea production in the active snail and in the snail revived after aestivation was suggested to be through uricolysis<sup>3</sup>. The significance of this circuitous pathway for the production of urea is hard to speculate at present. It may be inferred that on aestivation the uricolysis is blocked and the snail stores all the nitrogenous wastes in the form of innocuous uric acid. The immediate survival demand against ammonia and urea toxicity might have made the animal prefer uric acid production though from the free energy point of view it is a costly waste product.

This research is supported, in part, by a grant from the US Department of Agriculture under P.L.-480 (A-7-ADP-31).

## BIOTIN DEFICIENCY AND PERMEABILITY CHANGE IN *ASPERGILLUS NIDULANS*

STUDIES conducted in our laboratory have shown marked reduction in the ability to synthesize fatty acids with concomitant increase in the protein content due to biotin deficiency in *Aspergillus nidulans*<sup>1</sup>. Rao and Modi<sup>2,3</sup> demonstrated the change in the fatty acid content of the cell wall-cell membrane fraction and the increased ammonia uptake due to the deficiency of biotin in *Aspergillus nidulans*. Reduction in the fatty acid content as a result of biotin deficiency has been well documented<sup>4,5</sup>. Comparatively, very little is known regarding the phospholipid content in biotin deficient cells. The present communication deals with the effect of biotin deficiency on phospholipid content and its role in uptake of various solutes.

The strain, the medium composition and the cultural conditions used in the present investigation were same as described earlier<sup>6</sup>. Total lipid was extracted with chloroform : methanol (2 : 1 v/v) and was freed from water soluble impurities by the method of Folch *et al.*<sup>7</sup>. Lipid obtained was chromatographed on thin layer plates (0.5 mm thick) of silica gel, H. (E Merck) as described by Yano *et al.*<sup>8</sup>. Total lipids were visualized by heating the plate at 150°C for 45 mins, after spraying with concentrated H<sub>2</sub>SO<sub>4</sub> : saturated solution of K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> in water (7 : 3 v/v). For identification of each phospholipid, bands were detected with 2'-7'-dichlorofluorescein, scraped off with razor blade and recovered in chloroform : methanol (1 : 2 v/v). Phosphorus, amino group, reducing sugar and choline were detected by Dittmer's reagent<sup>9</sup>, ninhydrin, anthrone and Dragendorff's reagent<sup>10</sup> respectively. Quantitative assay of each phospholipid was performed by estimating the lipid phosphorus by the method of Bartlett<sup>11</sup>. This was also confirmed by the gravimetric analysis.

Uptake studies were carried out as described earlier<sup>6</sup>. Glucose, ammonia, potassium, phosphorus and nitrate ion were estimated by the methods of Dahlqvist<sup>12</sup>, Fawcett and Scott<sup>13</sup>, Loony and Dyer<sup>14</sup>, Fiske and Subba Row<sup>15</sup> and Goldsmith *et al.*<sup>16</sup>, respectively. From the initial values the rate of uptake was calculated.

Preliminary data indicated about 30% loss in the total phospholipid content due to biotin deficiency. No qualitative difference in the lipid synthesized by biotin deficient and normal cultures was observed. When these phospholipids were analyzed quantitatively, it was observed that biotin deficiency caused a major change in the content of phosphatidylinositol, phosphatidylserine, phosphatidylcholine and phosphatidylethanolamine (Table I).

TABLE I

Phospholipid content of biotin deficient *A. nidulans*

| Phospholipid             | Content (% mg) |           |
|--------------------------|----------------|-----------|
|                          | Normal         | Deficient |
| Lysophosphatidylcholine  | 0.400          | 0.380     |
| Phosphatidylinositol     | 0.136          | 0.095     |
| Phosphatidylserine       | 0.220          | 0.172     |
| Phosphatidylcholine      | 0.622          | 0.386     |
| Phosphatidylethanolamine | 0.439          | 0.162     |
| Cardiolipin              | 0.156          | 0.137     |
| Glycolipids              | 0.086          | 0.082     |
| Phosphatidic acid        | 0.109          | 0.110     |
| Neutral lipids           | 0.152          | 0.119     |

The role of biotin in fatty acid synthesis is well established and fatty acids are known to be one of the constituents of phospholipid. Rao and Modi<sup>1</sup> have shown that the fatty acid content decreases due to the deficiency of biotin in this culture. Thus, the effect of biotin deficiency on phospholipid content may be of secondary one, preceded by the inhibition of fatty acid synthesis.

TABLE II

Uptake of various nutrients by biotin deficient *A. nidulans*

| Nutrient   | Uptake rate ( $\mu$ moles/gr dry cells/10 min) |           |
|------------|--|-----------|
|            | Normal   | Deficient |
| Glucose    | 8.33   | 6.66      |
| Ammonia    | 36.50  | 48.50     |
| Nitrate    | 26.40  | 26.45     |
| Phosphorus | 7.10   | 10.03     |
| Potassium  | 6.90   | 9.18      |

Results listed in Table II suggest that during biotin deficiency there is a change in the permeability of the mold. The results have to be confirmed using labelled substrates in short term experiments. Rao and Modi<sup>2</sup> showed increased ammonium ion uptake by biotin deficient culture, compared to that of normal culture of *A. nidulans*. Earlier, we demonstrated the decreased ability to take up glucose due to biotin deficiency in *A. nidulans*<sup>3</sup>. Further studies showed that glucose binding protein is involved in glucose transport in

this culture<sup>4,5</sup>. The role of phospholipids in membrane transport is well established. Several investigators<sup>6-10</sup> have reported that the properties of membrane transport is affected by the fatty acids incorporated into membrane phospholipid. Thus, the data suggest that the decrease in the phospholipid content due to biotin deficiency may be one of the causes for alteration in the permeability to various nutrients in *A. nidulans*.

#### A NEW ANTIFUNGAL ANTIBIOTIC PRODUCED BY A SOIL STREPTOMYCETE

As a result of an extensive search for new and useful antimicrobial agents that are produced by soil microorganisms, the authors have been able to isolate a strain of *Streptomyces* sp. designated as Ac<sub>2</sub>, which showed wide antifungal activities. The active material was extracted, purified and characterized as a new polyene antifungal antibiotic, A-2.

The organism was grown in shake flasks at 28° C for 5 days in a medium containing sucrose 20.0, NaNO<sub>3</sub> 3.0, KCl 0.32, NaH<sub>2</sub>PO<sub>4</sub> 0.032, and MgSO<sub>4</sub> · 7 H<sub>2</sub>O 0.016 g/l (pH 6.5). The antibiotic was extracted from the culture filtrate with *n*-butanol, the butanol extract was concentrated and chilled. The active material, which separated as a precipitate from the inactive supernatant, was dried and dissolved in methanol. By repeated addition of cold ether to the methanol solution and chilling a precipitate was obtained which was finally dried *in vacuo*. A-2 was obtained as sulphur yellow powder.

The antifungal spectrum of A-2 as determined by agar-cup method of assay, is presented in Table I.

TABLE I  
Antimicrobial activity of A-2 as determined by the  
agar cup method of assay

| Test organisms                     | Minimum inhibitory concentrations (µg/ml) |
|------------------------------------|---|
| <i>Saccharomyces cerevisiae</i> .. | 1.0                                       |
| <i>Candida albicans</i> ..         | 2.0                                       |
| <i>Aspergillus niger</i> ..        | 50.0                                      |
| <i>Curvularia lunata</i> ..        | 2.0                                       |
| <i>Fusarium udum</i> ..            | 15.0                                      |
| <i>Alternaria solani</i> ..        | 12.0                                      |
| <i>Helminthosporium oryzae</i> ..  | 2.0                                       |
| <i>Blastomyces dermatitidis</i> .. | 0.8                                       |
| <i>Sporotrichum scheinkii</i> ..   | 60.0                                      |
| <i>Microsporum gypseum</i> ..      | 80.0                                      |

The substance is homogeneous as found by paper electrophoresis, paper and thin layer chromatographic studies. A-2 is soluble in water, methanol, ethanol and *n*-butanol, insoluble in chloroform, ether, petroleum ether and acetic acid. It is amphoteric in nature, melts at 142° C (decomposition), optical rotation ( $\alpha_D^{25}$ ) = +50° (C 2% methanol). The ultraviolet absorption spectrum in methanol showed maxima at 360, 380 and 402 m $\mu$  indicating a heptaene compound<sup>1</sup>. Micro-analytical data showed C 41.21%, H 7.14%, N 1.45% and O 50.20% (by difference). The infrared absorption spectrum of A-2 indicated the presence of hydroxyl group at 3350 cm<sup>-1</sup>, either an ester or a lactone at 1710 cm<sup>-1</sup> and a polyene system at 1640 cm<sup>-1</sup>. The band at 920 cm<sup>-1</sup> could be attributed to a disubstituted *trans* double bond system.

The antifungal and physico-chemical properties of A-2 indicate that it is a polyene antibiotic and belongs to the group of heptaenes and to the type of non-aromatic heptaenes<sup>2</sup>. Literature was surveyed extensively to determine the identity of A-2. Comparative studies with known non-aromatic

heptaenes such as amphotericin B<sup>3</sup>, candidin<sup>4</sup>, mycoheptin<sup>5</sup> and blimyacin<sup>6</sup> showed that A-2 is different from these antibiotics in its physico-chemical and antimicrobial properties.

Our thanks are due to Drs. S. M. Sircar and P. Nandi, Director and Head of the Microbiology Department, for their kind help and interest in our work.

#### VARIETAL TOLERANCE TO LOW PHOSPHORUS CONDITIONS\*

STUDIES to evaluate the rice varieties suitable for low phosphate conditions were carried out in field and greenhouse at the national headquarters of the All India Coordinated Rice Improvement Project (AICRIP). In one such field experiment, 110 rice varieties including both tall and dwarfs were grown on a black clay soil (pH 7.8, O.M. 2.0%, CEC 42 m.eq./100 g soil, Olsen's P 1.4 ppm, P absorption coefficient 1300 mg/100 g P<sub>2</sub>O<sub>5</sub>) well supplied with N, K and Zn. Almost all the varieties failed to establish under the no-phosphorus treatment, whereas those that survived gave appreciable yields, when 90 kg P<sub>2</sub>O<sub>5</sub>/ha were added. IET 3162, IET 3444 bore a few tillers and gave a low yield (computed to be less than 1.2 t/ha) only in one of the three replicates under no-phosphate. H 4, a tall variety from Sri Lanka, known for its resistance to phosphorus deficiency (Ponnamperuma and Castro, 1972) was among those that failed to survive. It can thus be concluded that pronounced varietal differences do not exist for reactions to low available P below a critical level.

Based upon the results of the preceding study, in a follow-up experiment involving twelve varieties, graded levels of phosphorus were added to a similar soil (Olsen's P 1.0 ppm) in cement pots (40 cm × 40 cm × 52 cm deep). The findings of this experiment are as follows:

### Phosphorus Deficiency

Severe phosphorus deficiency symptoms, such as chlorosis along the margins of the lower leaves followed by scorched appearance and drying, reduced tillering and growth, erect spindly leaves with dirty dark green colour were observed in all the varieties, within 10-12 days of planting, in the no-phosphorus as well as 10 kg  $P_2O_5$  ha treatments. Severity of symptoms decreased with the increased level of P application. The intensity of symptoms on 60th day after planting in different varieties was as follows:

Moderate ... IR 1514A-E666, RPA 5929  
Severe ... RPA 5824, IET 3162, RP 4-17,  
Kumar, Pokkali, Pelita 1/1,  
and IET 3444.  
Very severe ... IET 3166, MI 48, and H4.

### Tiller Number and Grain Yield

Data for tiller number, 60 days after planting (Table I), and grain yield (Table II) reveal the following:

TABLE I

Tiller number of certain rice varieties 60 days after transplanting under different levels of phosphorus

| Variety            | Levels of P ( $P_2O_5$ kg ha) |    |    |    |    |
|--------------------|-------------------------------|----|----|----|----|
|                    | 0                             | 10 | 20 | 30 | 40 |
| RPA 5824           | 0                             | 1  | 6  | 5  | 8  |

| IR 1514 A-E 666      | 0                             | 0  | 8.7 | 9.2  | 11.7 |
| Pelita 1/1           | 0                             | 0  | 0.4 | 1.3  | 5.6  |
| IET 3444             | 0                             | 0  | 0.2 | 1.6  | 4.0  |

1. None of the varieties produced any grain in no-phosphorus treatment.

2. Except IR 1514 A-E 666, no variety produced tiller when 10 kg  $P_2O_5$  ha was applied. None of the varieties, including IR 1514 A-E 666, could produce any grain yield.

3. With 20 kg  $P_2O_5$  ha treatment Kumar, MI 48, Pokkali and H4 failed to tiller. These varieties including IET 3166 did not give any grain yield. On the other hand IR 1514 A-E 666 which produced the highest number of tillers (16 tillers hill) gave the highest grain yield (8.7 g.). Remaining varieties produced 3-6 tillers and gave grain yield varying between 0.2 to 2.0 g.

4. At 30 kg  $P_2O_5$  ha Pokkali gave the highest grain yield followed by RPA 5929 and IR 1514 A-E 666. Pokkali although had less tiller production at 60 days yet produced more grain. This was because of continuous tiller production even after 60 days (Pokkali is a late variety).

IR 1514 A-E 666 on the other hand although had maximum tiller number yet produced less. This is mainly due to its shattering habit.

Remaining varieties except IET 3162 produced less than 5 g. MI-48 and H4 failed to produce any grain.

5. At 40 kg  $P_2O_5$  the trend in tiller production and grain yield were more or less similar to 30 kg  $P_2O_5$  ha treatment. However, MI-48 gave moderate yield at this level, while H4 failed to produce any grain.

The data on symptoms, tiller number and grain yield clearly demonstrated that IR 1514-E 666 and RPA 5929 are the most efficient in this set of varieties in utilizing the small amounts of added phosphorus. While Pokkali produced the highest yield at higher levels of phosphorus, in actual field conditions under community planting, in view of its poor plant type it is not expected to excel the performance of IR 1514 A-E 666 and RPA 5929. IR 1514 A-E 666 has been reported to be tolerant to low phosphorus conditions at IRRI (Ponnamperuma, 1974). But this variety has other defects, such as shattering and susceptibility to tungro virus. RPA 5929, on the other hand, is reported to possess resistance to bacterial leaf blight, stem borer, gall midge, and green leaf hopper, besides being of mid-duration and having medium slender grains and high yield potential (Seshu *et al.*, 1974, in press). H4, a tall variety from Sri Lanka, reported to be resistant to low P (Ponnamperuma and Castro, 1972) was the most susceptible in our tests. H4 has been bred and grown under low pH conditions in Sri Lanka. Its resistance to low phosphorus has been tested by IRRI soil chemists on an acidic soil (Louisiana clay pH 4.7), unlike

(pH 7-8). Phosphorus in acidic soils is present as iron and aluminium phosphates, whereas under our tests which were performed on an alkaline soil alkaline conditions it is chiefly as calcium phosphate. It is possible that H<sup>+</sup> may be capable of utilizing iron and aluminium phosphates resulting in a fair degree of tolerance to low phosphorus under acidic conditions, whereas it may not have capacity to use calcium phosphates. It is, therefore, essential that when varieties are tested for their tolerance to adverse soil conditions, the relevant soil properties have also to be taken into consideration.

#### A NONPIGMENTED STRAIN OF *XANTHOMONAS AZADIRACHTII* MONIZ AND RAJ. CAUSING LEAF SPOT OF NEEM (*AZADIRACHTA INDICA* A. JUSS)

Neem (*Azadirachta indica* A. Juss) is an important medicinal evergreen tree on which two bacterial diseases, viz., leaf blight and spot caused respectively by *Pseudomonas azadirachtae* Desai *et al.*<sup>2,10</sup>, and *Xanthomonas azadirachti* Moniz and Raj.,<sup>8</sup> have been reported. During February 1972, severe leaf spot was observed on neem leaves near Jodhpur. A creamy white bacterium was isolated on nutrient agar the pathogenicity of which was proved by inoculating both young and old leaves of neem plant by rubbing the inoculum (ca. 108 cells/ml) mixed with carborundum powder and the same bacterium was reisolated from infected leaves.

The first symptom appears on the leaflets as small, translucent, watersoaked spots which later turn light brown to brown. These spots gradually increase in size coalesce and become necrotic from the centre. The coalesced lesions are often delimited by veins and veinlets giving angular appearance.

The infected leaves eventually become chlorotic, dry and defoliate prematurely.

Albino strains of xanthomonads are reported<sup>1</sup> and validity of some of the species has been doubted by Dye<sup>5</sup>. In India Durgapal<sup>3</sup> reported albino strain of *Xanthomonas uppalii* on *Ipomoea muricata* L. while Jindal and Patel<sup>6</sup> and Patel and Jindal<sup>9</sup> have reported albino strain and species of *Xanthomonas ricinicola* on *Ricinus communis* L. and *Xanthomonas pedatii* on *Pedaliu murex* L. respectively. The bacterium under study is identified as a nonpigmented strain of *Xanthomonas azadirachti* Moniz and Raj., 1967, the bacteriological studies of which are given as follows:

The bacterium is rod shaped, gram negative and weakly motile. On nutrient agar the colonies are round with entire margins, smooth, raised, shining and white in colour. The colony characters on GYCA<sup>4</sup> and PDA<sup>1,4</sup> are the same as observed on nutrient agar except that they are brown on GYCA and creamy white on PDA. Growth on potato wedge was slimy, shining and creamy white in colour. This bacterium did not grow on Kado's<sup>7</sup> medium specific for *Pseudomonas* spp. but grows though slowly on Kado's medium specific for *Xanthomonas* spp.

The bacterium did not utilize asparagine as sole source of carbon and nitrogen; produced H<sub>2</sub>S from cysteine; starch hydrolysed; indole, V.P. and M.R. tests negative; gelatin liquefaction slow; catalase positive; did not reduce nitrate; urease test negative with thymol blue indicator; utilized glucose oxidatively; sodium citrate, succinate, acetate and propionate were utilized but not tartrate and lactate. Growth excellent at 28-30° C, good at 25-34° C, poor at 21° C, and no growth at 5-10° C and 40° C.

The bacterium did not produce symptoms when inoculated by carborundum method on any of the following plants: *Cajanus cajan* (Linn.) Millsp.; *Vigna sinensis* Sari.; *Cicer arietinum* Linn.; *Pisum sativum* Linn.; *Zea mays* Linn.; Wheat, Cotton. *Arachis hypogaea* Linn.; *Brassica oleracea* Linn. var. *capitata* Linn.; *Brassica oleracea* Linn.; var. *botrytis* Linn.; *Raphanus sativus* Linn.; *Solanum tuberosum* Linn.; *Lycopersicon esculentum* Mill.; *Citrus aurantifolia* Swingle; *Vitis vinifera* Linn.; *Amaranthus* sp., *Capsicum annuum* Linn.; *Solanum melongena* Linn.; *Spinacia oleracea* Linn.; *Allium cepa* Linn.; *Ficus religiosa* Linn.; *Phaseolus mungo* Linn.; *Cyamopsis tetragonoloba* (Linn.) Taub.; *Psidium guajava* Linn.; *Mangifera indica* Linn.; *Punica granatum* Linn.; *Rosa* sp., *Tecoma* sp., *Phaseolus aureus* Roxb., *Sesamum indicum* Linn.; *Bougainvillea* sp. and *Duranta* sp.

The culture was sent to Dr. J. F. Bradbury, Bacteriologist, C.M.I., Kew, England, who also

identified it as a nonpigmented strain of *Xanthomonas axadiaractii* (Acc. No. B 5643).

#### STRAINS OF TOMATO RESISTANT TO ROOT-KNOT NEMATODES (*MELOIDOGYNE* SPP.)

*Meloidogyne* spp. have become one of the major limiting factors for the successful production of tomato in most of the vegetable gardens. Improvement of crop plants with genetically built in resistance for nematodes is a well-known approach in plant protection research and a few tomato cultivars resistant to several species of *Meloidogyne* have been developed<sup>1,2</sup>. Varietal resistance, being heritable, is more reliable, inexpensive and eliminates pesticidal hazards. With this point in view and to develop resistant strains for nematodes, five hybrids of tomato (closed pedigree) were received from Dr. T. R. Everett, Ford Foundation Consultant in Entomology and were used as source material to develop pure lines.

In order to develop homozygous lines, the hybrids were allowed to segregate in root-knot nematode sick plots for five generations. Selection pressure was applied for both nematode resistance as well as for plants with high yield potential and optimum fruit size. Pedigree record was maintained throughout. Two lines possessing good agronomic characters were selected and tested for root-knot infection both in field and laboratory conditions. Under laboratory conditions, random sample of twenty plants from each line were grown in pots containing steam sterilized soil to which 1000 second stage larvae, obtained from the pure cultures of *Meloidogyne incognita* and *M. javanica*,

were inoculated. The susceptible variety of tomato 'Pusa Ruby' was used as control. The total number of root-knot galls per plant was recorded six weeks after inoculation.

It is apparent from data (Table I), that the selected lines were completely resistant to *M. incognita* and also showed a high degree of resistance

TABLE I  
Reaction of tomato variety/strain to the attack of *M. incognita* and *M. javanica*

| Variety/strain | Mean number of galls per plant |                    |
|----------------|--------------------------------|--------------------|
|                | <i>M. incognita</i>            | <i>M. javanica</i> |
| Pusa Ruby ..   | 206.8                          | 204.6              |
| Strain 1 ..    | 0.0                            | 4.4                |
| .. 2 ..        | 0.0                            | 7.8                |

to *M. javanica*. The concomitant studies made in the field, heavily infested with root-knot nematodes, also showed a very high degree of resistance. Variety Pusa Ruby was heavily infested and the plants were stunted with poor fruit set. In both the selected strains the plants were normal with a good bearing. The resistant lines appear to be very promising.

#### CARBOHYDRATE CHANGE IN THE HAEMOLYMPH OF *SPODOPTERA LITURA* (FABRICIUS) DURING THE COURSE OF NUCLEAR POLYHEDROSIS VIRUS DISEASE

TREHALOSE, the major blood sugar of the insect haemolymph varies with nutritional state<sup>1</sup>. Marked fall during several days of starvation has been observed in *Bombyx mori* L.<sup>2</sup>. There is no report on the carbohydrate changes in insects due to nuclear polyhedrosis virus (NPV) disease. However, van der Geest and Craig<sup>3</sup> suggested that the decrease in total solids in the haemolymph of NPV infected *Peridroma saucia* (Hubner) could possibly be due to depletion of food reserves (carbohydrates) in the haemolymph.

Six day old larvae of *S. litura* were fed with heavy suspension of polyhedra for 24 hr and fresh food was supplied thereafter. Haemolymph samples were collected at 24 hr interval for a period of 6

days. The total carbohydrate content of haemolymph after deproteinisation was determined by anthrone reagent<sup>1</sup> using *D*-glucose (AR-BDH) as standard and expressed in g/100 ml of haemolymph.

The carbohydrate contents of the haemolymph of normal and virus fed larvae determined during the course of NPV infection are given in Table I.

TABLE I

Carbohydrate levels (g/100 ml) in the haemolymph of normal and diseased larvae of *S. litura*

| Days after infection | Normal (Mean $\pm$ SD) | Diseased (Mean $\pm$ SD) | t test |
|----------------------|------------------------|--------------------------|--------|
| 1                    | 0.150 $\pm$ 0.010 (4)  | 0.150 $\pm$ 0.010 (3)    | NS     |
| 2                    | 0.230 $\pm$ 0.010 (3)  | 0.210 $\pm$ 0.010 (3)    | NS     |
| 3                    | 0.260 $\pm$ 0.022 (5)  | 0.250 $\pm$ 0.017 (5)    | NS     |
| 4                    | 0.610 $\pm$ 0.007 (5)  | 0.380 $\pm$ 0.006 (3)    | **     |
| 5                    | 1.060 $\pm$ 0.160 (5)  | 0.460 $\pm$ 0.024 (5)    | **     |
| 6                    | 1.110 $\pm$ 0.043 (5)  | 0.620 $\pm$ 0.012 (5)    | **     |

NS, Not significant. \*\* Significant at  $P=0.01$ . Figures in parentheses indicate the number of replicates.

Carbohydrate contents increased with age in both normal and virus fed larvae from an initial level of 0.15 g on the first day to 1.11 g and 0.62 g/100 ml, respectively, for normal and virus fed larvae on 6th day. The carbohydrate level remained almost the same for the first 3 days of observation in both the groups. Though, carbohydrate level increased in the virus fed larvae during 4-6 days of observation, the proportionate increase during this period was much lower compared to the normal larvae and was statistically significant.

Reduced glucose levels in the haemolymph were observed in the mollusc, *Biomphalaria glabrata* infected with larval trematode, *Schistosoma mansoni* after 3 weeks. This was attributed in part, to uptake and utilization by the parasite<sup>2</sup>. A similar reduction in trehalose level was reported in parasitised hornworm larvae, *Manduca sexta* (Johnson)<sup>3</sup>.

There appears to be striking correlation between the appearance of symptoms, food consumption and utilization, and carbohydrate levels in the haemolymph of virus fed larvae of *S. litura*. The carbohydrates got reduced in virus fed larvae during 4-6 days. Similarly, food consumption and utilization were reduced only after 3 days of virus infection (Ramakrishnan and Chaudhari, Unpublished).

It is surmised from these observations that reduced carbohydrate level in the diseased haemolymph of *S. litura* during 4-6 days is due to reduced food consumption which in turn results from virus multiplication.

## MORPHOLOGY AND GERMINATION OF *PTERIS CRETICA* SPORES

IN the study of *Pteris cretica* L. it was observed that this fern has bilateral as well as tetrahedral spores (Figs. 1 and 3) though normally this fern produces only tetrahedral spores. Panigrahi and Dixit (1969) found trilete and monolete spores in *Ophioglossum reticulatum*. These spores occur in separate sporangia which originate from the same sorus. Pant and Srivastava (1962) found trilete and monolete microspores in the same microsporangium in *Isoetes indica*. Occurrence of two different kinds of spores within two distinct types of sporangia (of the same size) is rare. Sporangia contain 40% bilateral spores while 60% are tetrahedral.

Tetrahedral spores (Figs. 1 A, B) are  $39 \times 42 \mu$ . They appear to be subtriangular in lateral view and are somewhat rounded in proximal view. They have a distinct trilete mark, each arm being  $22 \mu$  long. Exine is  $4 \mu$  thick and dark brown in colour. Sexine and nexine are not distinguishable. Exine is rugulose, rugulae appear as crenate projections.

Bilateral or monolete spores are  $55 \times 32 \times 45 \mu$  (Figs. 3 A, B) they are somewhat longer than the trilete ones. They appear to be planoconvex in lateral view and oval in proximal view. Laesura is  $32 \mu$ , the exine is  $4 \mu$  thick and light brown in colour. Exine ornamentation is identical with that of the tetrahedral spores.

Occurrence of both, tetrahedral and bilateral type of spores in *Pteris cretica* has not been reported earlier. Germination of both kind of spores has been studied and is reported below:

Both types germinate after the 5th or the 6th day after sowing. Tetrahedral spores germinate to produce a rhizoidal and a body cell. The latter has numerous chloroplasts (Fig. 2 A). This cell divides transversely a number of times to produce a filament of 4 to 5 cells in 3 days (Figs. 2 B, C, D, E). This filament is comparatively smaller in size as compared to that produced by bilateral spores. The filament remains in this stage for 10 to 12 days. Now, the terminal cell undergoes vertical division (Fig. 2 F). Subsequent divisions form a flat, fan-shaped structure which ultimately

develops into a cordate prothallus (Fig. 2G) with fewer rhizoids as compared with the bilateral spores.

Bilateral spores germinate to produce a rhizoidal and a body cell, the latter is comparatively long (Fig. 4A), 4 to 5 celled stage is reached quickly in 24 hours (Figs. 4B, C, D). The terminal cell divides vertically on the 5th or the 6th day after germination (Fig. 4E). The number of rhizoids produced is more. The filamentous stage gets

changed soon into a cordate prothallus and progresses in vertical divisions (Figs. 4F, G and H).

Monolete spores take 11 days while the trilete ones take 20 days for the formation of a cordate prothallus almost equal size under identical conditions.

It is therefore concluded that the pace of development exhibited by bilateral spores is faster than that shown by the tetrahedral ones.

Figs. 1-4. Fig. 1. A. Trilete spore in lateral view. B. In proximal view. Fig. 2. A-G. Germination of tetrahedral spore of *Pteris cretica* showing stages in the development of prothallus. A-Germination on the 6th day after sowing of the spore showing body cell and a rhizoidal cell. B & C-2nd and 3rd stage of development on the 2nd day after germination. D-4th stage, 4 celled filament after germination on the 6th day. E-5th stage, 5 celled filament after germination on the 6th day. F-6th stage, apical cell of the filament divides vertically on the 10th day. G-7th stage, apical notch is formed and beginning of the usual cordate shaped prothallus on the 20th day after germination. Fig. 3 A-Monolete spore proximal view. B-Lateral view. Fig. 4. A-H. Germination of bilateral spore of *Pteris cretica* showing stages in the development of prothallus. A-1st stage of germination on the 6th day of sowing of spores showing body cell and rhizoid. B & C-2nd and 3rd stage of development on the 2nd day after germination. D-4th stage, filament having many cells and 3 rhizoids on the 3rd day of germination. E-5th stage, terminal wall of the filament showing vertical division on the 6th day after germination. F-6th stage, spatulate stage reached on the 10th day after germination. G-7th stage, spatulate part becomes wider on the 10th day after germination. H-8th stage, apical notch is formed and cordate shape of prothallus becomes discernible on the 11th day after germination.

### EFFECT OF KINETIN ON THE SEX RATIO IN *DROSOPHILA MELANOGASTER*

CYTOKININS have been shown to induce a shift in sex balance towards femaleness in hermaphrodite flowers<sup>1</sup>, and the male flowers into a hermaphrodite<sup>2</sup>. Other phytohormones like gibberellic acid<sup>3</sup> and ethylene<sup>4</sup> are known to change the balance in sex in plants.

Isopentenyladenosine, a cytokinin, has been shown to promote growth as well as inhibit growth in human cells (lymphocytes) depending upon the concentration<sup>5</sup>. A few other studies also show some physiological effects of cytokinins in animal cells<sup>1</sup>.

The present investigation was carried out to study the formative effects, if any, of kinetin on *Drosophila melanogaster*. Kinetin at three concentrations, viz., 300 ppm, 200 ppm and 100 ppm were incorporated into the corn meal agar media and 20 pairs of male and female of Wild type flies were released into the media. Each treatment was replicated thrice with controls. A concentration of 300 ppm kinetin was toxic and the larvae did not survive. Morphological observations revealed no abnormalities of any kind but for the sex ratio which was 1:1 in all the controls (kinetin-free). But in the kinetin supplemented media the sex ratio of  $F_1$  progeny was 1:1.5 in both treatments with 100 and 200 ppm of kinetin. A similar ratio (1:1.5) in  $F_2$  and  $F_3$  generations was also observed (Table I). To know whether kinetin induced a permanent change in the sex ratio, the progeny from the kinetin supplemented media were transferred to kinetin-free media, and it was observed that the sex ratio reverted back to 1:1. The kinetin induced change in sex ratio was therefore purely temporary and was not heritable.

TABLE I

Population of males and females grown on kinetin supplemented media and controls for generations

|                             | 100 ppm |        | 200 ppm |        | Control |        |
|-----------------------------|---------|--------|---------|--------|---------|--------|
|                             | Male    | Female | Male    | Female | Male    | Female |
| (Average of 3 replications) |         |        |         |        |         |        |
| Generation                  |         |        |         |        |         |        |
| $F_1$                       | 221     | 323    | 257     | 359    | 259     | 279    |
| $F_2$                       | 140     | 266    | 235     | 353    | 251     | 274    |
| $F_3$                       | 190     | 242    | 166     | 238    | 114     | 127    |

$X^2$  values significant for all the three generations at 5% level.

The above results indicate kinetin acts like a phenocopy inducing agent, acting on the sex ratios in *Drosophila melanogaster*.

### ROOTING RESPONSE OF TEA CUTTINGS TO 'ALAR-85'

It has been reported that N, N'-dimethylamino-succinamic acid ('Alar-85') is promising for promoting rooting of cuttings of several ornamental species. (Read and Haysler, 1970 cited by Wittwer, 1971). In experiments carried out recently (October to December, 1974) we observed that this growth substance is useful in inducing abundant root formation in tea cuttings.

The standard technique of rooting 'leaf and internode' cuttings (Eden and Bond, 1941) was followed. Green wood cuttings of a good rooting tea clone 'B/6/29' were treated with 'Alar-85' at the concentrations of 2,500, 5,000, 7,500 and 10,000 ppm in 50% ethyl alcohol. The quick-dip method was adopted and 4 to 6 mm of the basal ends of the cuttings were immersed in the respective solutions for 5 seconds and were inserted in the rooting medium (sandy loam with a pH of 5.3). In our earlier trials, treating tea cuttings with 50% ethyl alcohol did not show any effect on inducing rooting of cuttings (Venkataramani, K. S., unpublished) and therefore in all our later experi-

TABLE I  
Effect of treatment with 'Alar-85' on rooting of tea cuttings

\* At the final examination.

ments we have been using only the untreated series of comparison purposes. Each treatment consisted of 100 cuttings. 10 cuttings from each treatment were examined at the end of 4 weeks. When the experiment was terminated at the end of 8 weeks all the remaining cuttings were examined. The results obtained are presented in Table I.

The cuttings treated with 'Alar-85' at the concentration of 2,500 ppm showed a greater percentage of rooting, more number of roots per cutting and a greater number of cuttings rooted earlier than the untreated ones. It was further observed that treatment with 'Alar-85' at this concentration resulted in a better root system (Fig. 1). The chemical inhibited rooting at very high concentrations (7,500 and 10,000 ppm). At 10,000 ppm shedding of the mother leaf occurred in 21% of the cuttings between the 4th and 8th week after treatment.

FIG. 1. Effect of 'Alar-85' on rooting of the cuttings of clone 'B/6 29': (a) Untreated. (b) 2,500 ppm. (c) 5,000 ppm.

I am thankful to Dr. K. S. Venkataramani, Director and Dr. V. S. Sharma, Botanist, UPASI Tea Research Station for helpful criticism of the script and for their interest in the investigation.

### MOSAIC VIRUS OF *ERYSIMUM HIERACHIFOLIUM* LINN.

A SEVERE mosaic disease on the leaves of *Erysimum hieracifolium* Linn. plants was noticed during May 1972 at the Horticultural Research Station, Simla. *E. hieracifolium* is perennial and an important medicinal plant which grows wild at higher altitude ranging from 2,000 metres to 4,000 metres. The characteristic symptom of the disease on the infected leaves showed the presence of green yellow patches which later diffused and entire leaf became discoloured. The leaves exhibited marginal curling and reduction in leaf lamina. The infected plants were stunted as compared to healthy ones. The transmission test by means of seeds procured from diseased plants was unsuccessful. However, this causal agent was successfully transmitted through insect vectors as well as the juice extracted from the diseased leaves establishing the viral nature of disease.

The virus was readily transmitted by the juice extracted from the diseased leaves of *Erysimum* plants which were growing wild in the field. The carborundum 600-mesh was applied on the healthy leaves as an abrasive before the inoculation. A large number of plants comprising of both cruciferous and non-cruciferous were used in the experiments. The plant species which could be infected mechanically were *Brassica chinensis* L., *B. juncea* (L.) Coss., *B. hirta* Moench, *B. integrifolia* O.E. Schultz., *B. nigra* (L.) Koch and *Nicotiana tabacum* L. var. White Burley. However, *Brassica oleracea* L., *Capsicum annum* L., *Chenopodium amaranticolor* Cosse and Reyn., *Cucumis sativus* L., *Datura stramonium* L., *Gomphrena globosa* L., *Phaseolus vulgaris* L., *Raphanus sativus* L., *Spinacea oleracea* L., *Vigna sinensis* Savi and *Zea mays* L., were found to be immune to the virus. The finding

was confirmed by back inoculation from test plants to original host which indicated the absence of the virus infection in the plants inoculated.

The physical properties of the virus indicated that this was inactivated when heated for 10 minutes at 50° C to 55° C. The dilution end point between 1 : 1000 to 1 : 1500 and remained infectious in the sap when stored at 15° to 18° for 10 days.

*Myzus persicae* Sulz., *Brevicoryne brassicae* (L.) and *Aphis gossypii* Glov. were employed for the study of insect transmission of the virus. Both viruliferous nymphs and adults of all three species of aphids were found to be capable of transmitting the disease in non-persistent manner from the infected leaves of *Erysimum* plants to *Brassica chinensis*, *B. nigra* and *B. juncea*. The virus was then recovered from these hosts to *Erysimum* plants by back inoculation.

The present studies of *Erysimum* mosaic virus revealed that the causal agent is transmitted by aphids and also by sap. The host range, physical properties and insect vectors are similar to that of Chinese Sarson mosaic virus as described by Azad and Sehgal<sup>1</sup>. Although slight variations in dilution end point and longevity *in vitro* of the virus were

noticed. It is therefore, concluded that the mosaic virus infecting *Erysimum* plants is related to Chinese Sarson mosaic virus, though it differs slightly in its physical properties. The occurrence of similar virus has also been reported on *Helipterum* (*Acroclinium*) *roseum* by Vashisth<sup>2</sup> causing mosaic symptoms. Since *E. hieracifolium* plant happens to be perennial and natural host it may act as potential source of Chinese Sarson mosaic virus.

Sincere thanks are due to Dr. R. N. Singh, Head, Division of Horticulture and Fruit Technology and to Dr. S. P. Raychaudhuri, Head, Division of Mycology and Plant Pathology, I.A.R.I., New Delhi, for their encouragement and providing facilities. The author is also grateful to Regional Botanist, Botanical Survey of India, Dehra Dun for identification of host plant.

## CURRENT SCIENCE

*Fortnightly Journal of Research*

Issued on the 5th and 20th of each month

### IMPORTANT NOTICE TO SUBSCRIBERS OF THE JOURNAL

As you are aware CURRENT SCIENCE has been coming out regularly on the due dates as above with the kind co-operation of you all.

On account of the sharp increase in the cost of quality paper used for the Journal, increase in rates of block making materials, increase in postal rates and the increase in the establishment charges it has become impossible for the Association to issue the Journal, unless the subscription rates are put up.

The Working Committee of the Association has reluctantly decided at its last meeting, to enhance the subscription of CURRENT SCIENCE with effect from 1st January 1975 for institutions :

India Rs. 84/- Foreign Rs. 150.00 S 20.00 or £ 8.0.0

The subscription rates for individual subscribers however will remain the same as now.

The continued co-operation of our subscribers is requested.

Bangalore-6  
30th July 1974

S. R. S. SASTRY  
Manager  
Current Science Association

## A New Indicator for Direct EDTA Titration of Ferric Ions

Salicylic acid and its related compounds<sup>1</sup>, ortho-hydroxy ketones and their oximes<sup>2</sup>, protocatechuic aldehyde and its related compounds<sup>3</sup>, cinnamohydroxamic acid, *n*-sulfophenyl hydroxamic acid, *n*-benzoyl-*n*-phenyl hydroxylamine and *n*-phenyl hydroxamic acid<sup>4</sup>, 4-OH-1-*p*-sulfonate phenyl triazine<sup>5</sup> and a number of substances have been used as indicators for direct EDTA titration of ferric ions, while aluminon has not been investigated as an indicator. This article reports the use of aluminon as an indicator for the direct titration of ferric salts with EDTA solution.

The stock solutions of ferric nitrate, EDTA and the indicator were 0.1 M, 0.01 M and 1.0% respectively. Solutions of interfering ions were 0.2 M. The Fe<sup>3+</sup> solution was standardised gravimetrically as ferric oxide.

Aluminon gives a violet colour with ferric ions. There is a sharp colour change on titration with EDTA from violet to pale yellow at the end point. When an aliquot of Fe<sup>3+</sup> is titrated with EDTA, iron can be estimated accurately in the PH range 2.0-3.0 with the help of the indicator investigated. Titrations carried out with different concentrations of the indicator, showed that an addition of 2 drops of 1.0% solution of the indicator gave satisfactory results for 5-10 ml of 0.01 M ferric nitrate solution. The titration could be satisfactorily carried out in the temperature range 10-60° C. At 2.8 mg concentration of iron, 50 times excess of Na<sup>+</sup>, K<sup>+</sup>, NH<sub>4</sub><sup>+</sup>, Cl<sup>-</sup>, NO<sub>3</sub><sup>-</sup>, SO<sub>4</sub><sup>2-</sup>, 10 times excess of Ni<sup>2+</sup>, Co<sup>2+</sup>, Mg<sup>2+</sup>, Mn<sup>2+</sup> and 5 times excess of Ca<sup>2+</sup>, Sr<sup>2+</sup>, Ba<sup>2+</sup>, Cr<sup>2+</sup> and Cu<sup>2+</sup> could be tolerated. Similar observation with other indicators have been reported by Desai and co-workers<sup>6,7</sup>.

Take 5.0 ml aliquot of 0.01 M ferric nitrate solution, adjust pH 2.0-3.0 using 1-2 ml of acetate-HCl buffer of pH 2.0, add 2 drops of 1.0% solution of the indicator and titrate against 0.01 M solution of EDTA to pale yellow colour.

5.0 ml aliquots of 0.01 M ferric nitrate were analysed according to the suggested procedure. The standard deviation was 1.0%.

Thanks are due to the Principal, Borsad Science and Law College and E.M.H.S. Trust, Borsad, for extending laboratory facilities.

## Amitrole Toxicity to Crops and its Reversal by Urea

A critical assessment of response of the crops against herbicides is certainly essential. In this experiment pearl millet and cotton seeds were supplied with 2 ml of amitrole 3 amino-*s*-triazole of 10 and 20 ppm respectively. Urea preparations of various concentrations (ppm) were added after two days. Seeds were allowed to grow in petri-dishes and chlorophyll from the first formed leaves was estimated.

It was noted that with 5 ppm of amitrole, millet leaves appeared less green and at 10 ppm became white while in cotton leaves became yellowish at 20 ppm, but no reduction in size of seedlings was noted. At 50 ppm the seedling length was reduced by 13.9% and 7.2% in pearl millet and cotton respectively. The chlorophyll content in millet was reduced to 0.07 mg/g fresh weight in contrast to 4.17 mg/g of the untreated ones. The chlorotic effect could gradually be removed with urea treatment and complete recovery was possible with 500 and 750 ppm in millet and cotton respectively.

Biological properties of amitrole as potent herbicide were described by Behrens (1953). Hall (1954) expressed that lower dosages of amitrole stimulated growth and higher dosages (about 210 to 420 ppm) were chlorotic. The results of the present investigation pointed that even 10-20 ppm of this herbicide can inhibit biosynthesis of chlorophyll in leaves of some crops. Though chlorosis and disorganised chloroplasts are the first symptoms of amitrole injury (Bartels and Weier, 1969) its recovery was not tried. The reappearance of

TABLE I

chlorophyll by treatment with urea, thus, appears to be of practical significance. However the fact that seedling length and area of leaves was not at all affected support Putala's (1967) finding that sublethal concentrations may not interfere with differentiation of other cellular organelles.

### Two Leaf Spot Diseases of *Zizyphus* from Haryana

*Zizyphus mauritiana* Lamk. is extensively planted in Haryana for the fruits. During February–March 1974 two leaf spot diseases were collected from Horticulture garden of Haryana Agricultural University, Hissar. The pathogens were fairly widely distributed on the host plant.

The first specimen revealed the formation of small dark-green to brownish spots on the leaves. The fungus was identified as *Cladosporium herbarum* (Persoon) Link. The pathogenicity was proved by inoculating the spore suspension on healthy leaves. It constitutes the first record of its occurrence from Haryana.

Another disease produced spots on the leaves, epiphyllous, yellow at first, then brown with a dark-brown margin, circular to oval, upto 4 mm in diameter, black, conidiophore 15–20 × 4 µ, straight, conidia 40–75 × 4 µ, the smaller one cylindric, the larger one clavate and tapering to 2 µ diameter (in nature) straight, ends obtuse, 3–8 septate, hyaline to olive-green in colour.

The present fungus is identified as *Cercospora zizyphi* Petch. It has also not been reported on *Zizyphus mauritiana* Lamk. from Haryana and constitutes a first record of its occurrence.

### *Brassica tournefortii* Gouan—A New Host of *Peronospora parasitica* (Pers.) de Bary

*Brassica tournefortii* locally known as *sodia* is grown in some parts of Haryana under rainfed conditions. During February to March 1974 the crop was found to be severely attacked by a downy mildew disease at research farm of Haryana Agricultural University, Hissar. Symptoms were noticed on the leaves, stem and pods in the form of characteristic purplish brown spots. The spots were small in the beginning but covered the whole surface of the leaves towards the end. A snow-white colour growth of the fungus occurs under surface of the leaves.

The fungus is identified as *Peronospora parasitica* (Pers.) de Bary. The present fungus has not been recorded on the above host and hence constitutes a new host record.

### New Host Records of Castor Semi-looper, *Achaea janata* L. (Lepidoptera: Noctuidae)

So far, castor semilooper (*Achaea janata* Linn.) has been reported to attack 26 host plants.

In the months of August and September, 1974, the authors found a large number of castor semilooper larvae feeding on the tender leaves of *Bauhinia purpuria* L., and the flower buds and floral parts of *Phaseolus aurens* L. at the Agricultural College Campus, Dharwar, Karnataka State.

The larvae when reared on plant parts of these new hosts successfully completed their life cycle. The two host plants thus, form new host records of *A. janata*.

***Muraya paniculata* Linn.—A New Host for *Diaphorina citri* Kuwayama**

*Muraya paniculata* Linn., a much valued flowering hedge was found severely attacked at the Landscape Nurseries of the Punjab Agricultural University, Ludhiana, during 1974 by *Diaphorina citri* Kuwayama. The attacked plant had abnormal appearance. The leaflets were yellow, curled and reduced in size. These leaflets dried up later and fell off prematurely. Average population of nymphs was found as high as 93 per leaf and 10–13 per leaflet.

The pest has been reported to attack almost all the species of citrus (Bindra<sup>1</sup>), Murwa (*Muraya koenigii* Speng) (Fletcher<sup>2</sup>) and Wampee [*Clausena lansium* (Lour) Skeels in China (Hoffman<sup>3</sup>)]. *Muraya paniculata* thus, appears to be a new host plant for *Diaphorina citri*.

**Association of 'Mudworm' *Polydora ligni* Webster with *Mytilopsis sallei* (Recluz) (Polycypoda)**

Among the several known species of *Polydora*, *P. ciliata*<sup>1-5</sup>, *P. websteri*<sup>6</sup>, *P. ligni*<sup>7</sup> and *P. hoplura*<sup>8</sup> have been frequently encountered as associates in shells of oysters from different countries. Incidence of *Polydora ligni* from Indian waters, however, has not been reported so far.

In the course of studies on the fouling bivalve *Mytilopsis sallei* (Recluz) incident at Visakhapatnam, 'blisters' were encountered in a large number of animals. Out of nearly 200 animals of *M. sallei* examined, about 20 specimens revealed the presence of these blisters which were found to harbour at least one worm each.

Regarding the nature of association of the worms with host some workers attribute oyster mortality to infection by *Polydora* sp. Extensive destruction of oyster beds in Australian waters has been attributed to infection by *P. ciliata* and *P. ligni*<sup>2</sup>. On examination of the nutritive value of infected and healthy oysters, Loosanoff and Engle<sup>2</sup> recorded that *P. websteri* did not cause any serious damage to the oysters in American waters but the same was stated to be responsible for the destruction of oysters in Dutch waters<sup>9</sup>. Presently no harmful effects could be noted in the host animals. It is, therefore, suggested that the association between *P. ligni* and *M. sallei* may be commensalic.

The authors are grateful to Dr. R. Philip Dales, Professor of Zoology, Bedford College, London, for valuable suggestions and critically reading the manuscript. Thanks are also due to Captain P. R. Sen, IN., Director and Sri. S. V. S. Rao, Deputy Director of this Laboratory, for their encouragement.

## INFORMATION TO CONTRIBUTORS

CURRENT SCIENCE is the Premier Science Fortnightly of India published by the Current Science Association, Bangalore and issued on the 5th and 20th of each month. All material intended for publication in CURRENT SCIENCE and books for review should be addressed to the Editor, *Current Science*, Raman Research Institute, Bangalore-560006.

The following types of Scientific Communications will be considered for publication :

- (i) Review articles on topics of major current interest not exceeding 4,000 words;
- (ii) Original Research Papers—not exceeding 2,000 words;
- (iii) Letters : These are brief reports of research of unusual and wide interest—they should not exceed 700 words in general;
- (iv) Short Scientific Notes—not exceeding 250 words.

Articles and papers should include a short abstract at the beginning.

References are indicated by superscripts in the text. The style of references should be *Journal* : The names of the authors, the journal, year, volume and page.

*Book* : Authors names, the title of the book, name and location of the publishers, year and page.

"Personal Communications" and "Unpublished Work" do not go into references and should be incorporated in the text. Acknowledgements should be brief.

Statements that the work is contribution No. .... of the Institute, declarations that the Director has authorised publications, etc., are not printed.

"Series" papers are discouraged.

Manuscripts, to be submitted in duplicate, should be typewritten in double space on one side of the paper, carefully revised and in final form for printing. Illustrations should be minimum in number, drawn in black and white with Indian ink on bristol board. Figures are usually reduced to one column width, and the originals should be about twice their final size.

No reprints are supplied gratis, but can be had on request at cost per V.P.P.

Business correspondence, remittances, subscriptions, advertisements, reprints, exchange journals, etc., should be addressed to the Manager, Current Science Association, Raman Research Institute, Bangalore-560006.

# solvents for spectroscopy

Modern spectroscopy in laboratory needs solvents of stringent purity for testing by Infra Red & Ultra Violet Spectroscopy.

The Label for products in this grade records guaranteed percentage transmittances at specified wave length in the ultra-violet region as criteria of purity.

Analysts can safely rely on our following range of solvents for optimum accuracy in spectrophotometric work:

- Acetone ◦ Benzene ◦ Carbon tetrachloride ◦ Chloroform
- Dichloromethane ◦ Methanol ◦ iso-Propanol

## ABSTRACT

It has been shown that the solar daily, seasonal, latitudinal and solar cycle variations of the occurrence of counter equatorial electrojet is consistent with the idea that these events are caused by the superimposition of the lunar geomagnetic field wave over the solar wave to produce the observed daily variation of the geomagnetic H field at any place. The mechanisms for the amplification of the lunar tidal oscillation on a particular day are still to be sought.

**B**ARTELS and Johnston (1940) were the first to point out large deformations and decreases in the geomagnetic H field at Huancayo during the daytime hours of a magnetically quiet day. They suggested that on these days, the lunar daily variation is magnified so many times, of its expected value that it may even be greater than solar daily variation on the same day. Onwumechilli (1963, 1964) found the existence of such big lunar-tide days at Ibadan, even on such days on which the phase of lunar wave was completely reversed. This phenomenon of the decrease of H field during the daytime at an equatorial station, now called 'counter-electrojet' has been observed at Addis Ababa (Gouin and Mayaud, 1967), Zaria (Hutton and Oyinloye, 1970), Kodaikanal (Rastogi, 1973) and other stations near the magnetic equator (Rastogi, 1974a).

Gouin and Mayaud (1967) suggested that there is no connection between the occurrence of counter-electrojet and the moon as the phenomenon has been observed at all times of the lunar day. Similar opinion was expressed by Hutton and Oyinloye (1970) even though they found that counter-electrojet occurs most frequently around 03 and 15 lunar hours. Onwumechilli and Akasofu (1972) showed that there are cases when the time of counter-electrojets at Huancayo were in complete anti-phase with the L field, and considered it as an evidence against association of all cases of  $S_q(H)$  depression with the moon. Sastri and Jayakar (1972) found that major depressions of the H field at Trivandrum occurred most frequently around lunar age 00 and 12 hr, and were practically absent around 06 and 18 hr lunar ages.

Rastogi (1973) suggested that the observed solar and lunar times of maximum occurrence of afternoon counter-electrojet events are due to the superposition of the L field on the average S field. On the same model, he predicted that the morning counter-electrojet events should be most frequent around lunar ages 06 and 18 hr. This has been confirmed later from the data of Huancayo, where the morning counter-electrojet was found to be most frequent around lunar ages 05 and 17 hr (Rastogi, 1974b).

Recently, Rastogi (1974a) has published the results of a detailed study of the daily, seasonal and solar cycle variations of the counter-electrojet at a number of equatorial stations. Some of the major highlights of the above study revealed that : (i) the counter-electrojet at equatorial stations occurs around 0700 and 1600 LT, (ii) the evening events are twice as frequent as the morning events, (iii) out of all stations studied, the events are most frequent at Kodaikanal and least frequent at Huancayo, (iv) the number of counter-electrojet events are inversely proportional to the solar activity, (v) at Huancayo, the evening counter-electrojet events are more than seven times more frequent during summer (June) than during winter (December) months. For Kodaikanal the corresponding ratio is only about 2, and (vi) the latitudinal extent of the counter-electrojet events is confined within  $\pm 5^\circ$  dip latitude. It is the aim of this paper to investigate whether all these points are consistent with the idea of counter-electrojet being the result of the superposition of lunar wave on the normal solar daily wave. Each of the points is discussed in turn. The basic idea is that for any solar time (T), the value of the H field would be above or below the nighttime base value depending upon whether  $\Delta H$  due to average  $S_q$  field is larger or smaller than the decrease of H due to the lunar daily variation for that hour and corresponding to the lunar age of the day concerned. The relative frequency of the counter-electrojet with any geophysical parameter would be directly related to the variation of the ratio  $M_2H/\Delta H$  with the above parameter.

The solar cycle and the seasonal effects in the lunar daily variation of the H field at the equatorial stations have been described for Huancayo by Rastogi (1968) and for Kodaikanal by Trivedi and Rastogi (1969). The present paper has derived the data from these publications for studying the ratio  $M_2H/\Delta H$ .

First we examine the lunar effect on the occurrence frequency of the counter-electrojet event. In Fig. 1 are plotted the percentage frequency of occurrence of the afternoon counter-electrojet

events at number of stations in terms of the lunar age ( $\gamma$ ) and separately in terms of the lunar time ( $\tau$ ). Some of the results by earlier workers are also included in the diagram. It is very clearly shown here that the occurrence of the counter-electrojet is intimately associated with the lunar age or with the lunar time. The counter-electrojet is most frequent at lunar age around 02 hr, i.e., two days after new or full moon. In terms of lunar time, the counter-electrojet is most frequent at about 03 lunar hour, i.e., about 3 hours after the upper or lower transit of the moon.

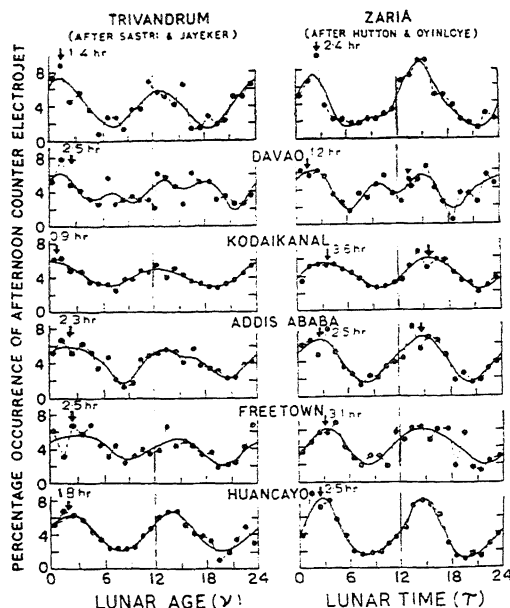

FIG. 1. The variation of the percentage occurrence frequency of the afternoon counter-electrojet events at number of equatorial stations as a function of lunar age and lunar time.

The lunar perturbations (due to semi-monthly wave) in  $\Delta H$  is known to be almost absent during the night hours and is maximum around midday (Rastogi and Trivedi, 1970). The lunar daily wave, however, has largest deviation at different solar time depending on the lunar age on that day. In Fig. 2 are shown the solar daily variation of  $H$  at Huancayo averaged over all quiet days of D-months in 1951-55. The deviation of  $H$  from this average curve is also shown for days with definite lunar ages; these curves show the lunar perturbation in terms of solar time. The largest deviation is seen on lunar ages 21 and 09 hr but the minimum occurs around 1000-1100 LT when  $\Delta H$  due to  $S_q(H)$  is comparatively much larger and so the lunar perturbations would not have any

apparent effect. On lunar ages 03 and 15 lunar hr large (about 10%) depression occurs around 1,600 LT when  $\Delta H$  due to  $S_q$  variation is less than 10%, and thus one may expect a negative value of  $\Delta H$  on those days due to combined effects of the moon and the sun. Thus the counter-electrojets in the evening hours are expected to be on days with lunar age around 03 or 15 hr. Similarly at the morning hours, large deviation in lunar wave comparable to  $S_q H$  at the same time, is expected on lunar ages around 18 and 06 hr. A more detailed picture can be obtained by studying the variation of the ratio  $(M_2/\Delta)H$  as a function of solar time. In Fig. 3, it is seen that although the maximum amplitude of lunar  $M_2(H)$  is about ten times smaller than the solar  $\Delta H$ , during the midday hours, the ratio  $(M_2/\Delta)H$  has two maxima in the morning and in the afternoon hours. The ratio is only about 0.1-0.2 during

FIG. 2. Average solar daily variation of  $\Delta H$  at Huancayo for D-months compared with the corresponding lunar daily variations on days of definite lunar ages.

midday but is about 0.3–0.8 during 0700 LT or 1600–1700 LT. These two times are approximately the times when the counter-electrojets are most frequent.

should be most frequent during D-months while at Kodaikanal seasonal variation ought to be very feeble, which is again consistent with the observed fact.

FIG. 3. The variation with the time of the day of the change of H field ( $\Delta H$ ), lunar semi-monthly tide in H ( $M_2H$ ) and the ratio  $M_2H/\Delta H$  for equatorial stations Huancayo and Kodaikanal for the year of low and high solar activity.

It is seen that on the average the ratio ( $M_2H/\Delta H$ ) is larger in the evening than in the morning hours suggesting greater probability of counter-electrojet in the evening than in the morning, which is consistent with the observed facts.

Examining the curves for the years of low and high solar activity, one finds that both  $M_2H$  as well as  $\Delta H$  are larger during years of high solar activity but the ratio  $M_2H/\Delta H$  is much smaller in the high than in the low sunspot years. This would suggest that the counter-electrojets should be less frequent during years of high sunspot number, which is again consistent with the observations.

It was also shown by Rastogi (1974a) that the number of afternoon counter-electrojet events at Huancayo is about 7 times more frequent in summer (D-months) than in winter (J-months); at Kodaikanal, the ratio is about 2 while at other stations the occurrence is practically independent of season. In Fig. 4 are shown the ratio  $M_2H/\Delta H$  at Huancayo and Kodaikanal as a function of local time for different seasons. It is seen that at Kodaikanal, the ratio is practically independent of season, but at Huancayo the maximum value of the ratio is about 1.8 in D-months and only 0.3 in J-months. Thus the counter-electrojet events at Huancayo

FIG. 4. The solar daily variation of the ratio of the amplitude of lunar semi-monthly tide in H ( $M_2H$ ) to the change in H from the mean nighttime level at each season of low and high sunspot years for Huancayo and Kodaikanal.

The diurnal, as well as seasonal variations of the occurrence of the counter-electrojet events at low-latitudes is consistent with the idea that the observed value of the H field is a combined effect of the solar variation and the lunar wave. There may be, of course, large deviations in this idea for individual cases of the counter-electrojet events.

## MEMORY SWITCHING OF THIN CdS FILMS

PYARE LAL, P. N. DIXIT AND S. K. SRIVASTAVA

*Radio and Electronics Research Laboratory, Department of Electronics Engineering,  
Institute of Technology, BHU, Varanasi 221005, India*

## ABSTRACT

Memory switching in thin CdS films has been studied and various switching parameters evaluated. The switching behaviour is attributed to the filling and emptying of barrier-surrounded traps whose existence is well defined.

## INTRODUCTION

**E**XTENSIVE studies have been made on memory switching of wide band-gap polycrystalline<sup>1,2</sup>, amorphous semiconductor materials<sup>3,4</sup>, various thin film heterojunctions<sup>5-7</sup> and other devices<sup>8,9</sup>. Memory in such a system has been attributed to a non-electronic process of phase transformation<sup>10</sup> or thermal diffusion of electrode metal<sup>11</sup>. However, these processes appear to be incapable of giving satisfactory explanation to the observed memory switching behaviour of the system. The present investigation has been made with a view to ascertaining the mechanism responsible for the observed behaviour in thin CdS films sandwiched between aluminium electrodes.

## EXPERIMENT

Thin films of CdS sandwiched between two aluminium electrodes were fabricated by vacuum evaporation technique on thoroughly cleaned glass slides by suitable masking arrangement. After each deposition, pellets of CdS were made before evaporation in order to avoid spurring of the material. The thickness of the film was monitored by the current through the heating filament and time of evaporation of CdS. Electrical contacts were made by pressure contact.

## RESULTS

The study of current voltage characteristic of the system exhibited two irreversible stages of conductivity. Initially a very low conductivity is observed and this is termed as virgin stage. This stage transforms irreversibly to a higher conductivity stage termed as post-breakdown stage, when the voltage across the sandwich exceeds a threshold value of about 7 to 10 volts. This stage exhibits memory switching between its two substrates of conductivity, viz., low and high conductivity states. An explanation to different breakdown potentials for transition has been given in terms of different effective ionized donor densities in the two states. This difficulty can be easily solved, if we know the contact field at breakdown. The contact field is

calculated to be of the order of  $10^6$  V/cm by using the well known expression<sup>12</sup>.

$$E = \left[ \frac{2qN(V + V_b)}{\epsilon\epsilon_0} \right]^{\frac{1}{2}}$$

where  $E$  is the contact field,  $V_b$  is the diffusion potential,  $q$  is the charge,  $\epsilon$  is the dielectric constant and  $\epsilon_0$  is the permittivity of the free space.  $V$  is the applied voltage and  $N$  is the ionized donor density.

Further, a detailed study of the conduction process of the system revealed that the conduction mechanism in both the stages of conductivity is due to field-induced generation of carriers followed by impact ionization.

The variation of current with voltage at different temperatures has been studied under steady-state conditions. The current decay after thermal stimulation gives the information about the energy and capture cross-section in the polycrystalline thin films. The current is observed to be time dependent and it assumes a steady state value after some time. All, but the shallowest traps are filled at room temperature when a fixed biasing potential is applied across the specimen. The number of majority carriers, i.e., ionized donor density, increases disturbing the equilibrium due to increase in the current. The trapping of excess carriers then takes place predominantly by shallow traps due to elevated temperatures. The decay of current, then starts taking place and after some time an appreciable fall is observed. Based on the above analysis of the current decay, two trap levels at 0.06 eV and 0.08 eV with respective capture cross-section  $4 \times 10^{-24}/\text{cm}^3$  and  $0.04 \times 10^{-24}/\text{cm}^3$  have been evaluated.

## CAPACITANCE STUDY

The study of the space charge capacitance of the diodes exhibited the existence of Schottky type space-charge capacitance due to thin aluminium oxide layer between bottom aluminium electrodes and cadmium sulphide. Further the ionized donor density in the pre-breakdown state is  $8.1 \times 10^{17}/\text{cm}^3$ .

$\text{cm}^2$  and in two reversible states are  $8.8 \times 10^{17}/\text{cm}^3$  and  $18.8 \times 10^{17}/\text{cm}^3$  respectively<sup>13</sup>. It is thus obvious from these data that the effective ionized donor densities in the pre-breakdown and low conductivity states are almost the same and show a marked variation from this value in the high conductivity stage.

The temperature variation of capacitance at low fixed bias voltage is shown in Fig. 1. This figure

FIG. 1. Variation of capacitance with (a) current and (b) Temperature (at 2 volts).

FIG. 2. The variation of capacitance with time (at 2 volts).

also shows the variation of capacitance with current at a constant voltage, current being changed by increasing the temperature. It is evident from this, that the capacitance and current

increase with temperature. The capacitance will increase only if trap ionization is the cause for increased current. Thus, it may be concluded that the major increase of the current with rising temperature is due to impact ionization of traps.

The capacitance of the system was also found to change its value with time immediately after a low bias was applied as shown in Fig. 2 which attains a steady value after about 25 minutes. The capacitance at fixed bias increases with time in the forward bias and decreases in the reverse bias operation. Furthermore this fall in capacitance was not observed when the sandwich was in the high conductivity state. It may, therefore, be concluded that the origin for both the phenomena, *i.e.*, change in capacitance and current with temperature are associated with ionization of slow traps.

### DISCUSSION

The inferences drawn from these experiments are used as a probe to explain the mechanism responsible for the observed memory switching behaviour of the system. The switching behaviour is attributed to either electrode metal diffusion, phase transformation or filling and emptying of barrier surrounded traps. The former alternatives, *i.e.*, electrode metal diffusion and phase transformation, do not yield satisfactory explanation to the change of donor density by a factor of two in different states of post-breakdown stage. The rapidity of the switching behaviour of the system also does not favour the idea of phase transformation. Cadmium sulphide in contact with aluminium oxide forms a depletion type of contact as shown in Fig. 3. Cadmium sulphide is an N-type semi-

FIG. 3. Energy Band diagram of Al-Al<sub>2</sub>O<sub>3</sub>-CdS Film.

conductor and hence electrons are depleted from aluminium oxide cadmium sulphide interface when positive voltage is applied to the top electrode of the sandwich. For larger voltage, impact ionization dominates field ionization. Thus by Avalanche process, trapping centres which are in excess near aluminium oxide-cadmium sulphide interface are emptied out. This causes an increase in the effective

ionized donor density and hence an increase in the field for the same voltage is achieved. The increase in the field will further enhance impact ionization and donor density further increases and the entire process becomes cumulative and instantaneous till all the traps are ionized and switching takes place. The transition from high to low conductivity state can be explained on similar lines. In this case negative bias is applied to the upper electrode (i.e., the direction of the bias is reversed). The reverse bias increases the width of the depletion region near cadmium sulphide aluminium interface and for large applied voltage, impact ionization supercedes field ionization. Thus warm electrons are generated near cadmium sulphide aluminium interface which are trapped by barrier surrounded trapping centres near oxide semiconductor interface. This reduces the effective ionized donor density thereby resulting in a decrease of conductivity.

#### CONCLUSION

It is thus concluded that the memory switching in the system considered is due to filling and emptying of barrier-surrounded traps, which change its occupancy and hence the conductivity at threshold voltage when switching takes place.

#### ACKNOWLEDGEMENT

The authors wish to record their sincere gratitude to Dr. S. S. Banerjee, UGC, Professor, for his encouragement throughout the course of the investigation. Thanks are also due to CSIR, India, for supporting the project.

### MAGNETIC PROPERTIES OF COPPER (II) COMPLEXES OF SCHIFF BASES DERIVED FROM PYRROLE-2-ALDEHYDE AND ISOPROPANOLAMINE/2-AMINO-2-METHYLPROPANOL

A. SYAMAL AND K. S. KALE

*Department of Chemical Technology, the University of Bombay, Matunga Road, Bombay 400019*

#### ABSTRACT

The synthesis of new copper(II) complexes of Schiff bases derived from pyrrole-2-aldehyde and isopropanolamine or 2-amino-2-methylpropanol is described. The Schiff bases coordinate through O, N and N as tridentate dibasic ligands. The complexes are characterised by magnetic susceptibility (84–294° K), infrared and electronic spectral studies. The magnetic moment of the copper (II) complex of pyrrole-isopropanolamine increases as the temperature is lowered indicating ferromagnetic nature of the complex while that of the copper(II) complex of pyrrole-2-amino-2-methylpropanol decreases with lowering of temperature indicating antiferromagnetic nature of the complex. The difference in magnetic properties has been attributed to the presence of steric hindrance arising out of two methyl groups in the latter complex.

#### INTRODUCTION

TRIDENTATE dibasic ligands yield metal complexes which frequently exhibit novel structural and magnetic properties<sup>1-3</sup>. The dibasic character of these ligands force the metal (II) ions to dimerise or polymerise leading to metal complexes with unusual magnetic properties. The size of the chelate rings influence the magnetic properties of the copper (II) complexes<sup>4</sup>. We now report the effect of steric hindrance on the magnetic behaviour

of the copper (II) complexes of Schiff bases. We have prepared new copper (II) complexes with the tridentate dibasic ONN donor ligands I and II and studied the magnetic properties of the complexes from 84 to 294° K.

#### EXPERIMENTAL

Pyrrole-2-aldehyde (0.02 M) was dissolved in 40 ml ethanol and isopropanolamine (0.02 M) was mixed with 10 ml ethanol. These solutions were

mixed and the mixture was refluxed on a water bath for 20 min. to give a yellow solution of the Schiff base. An aqueous solution of copper (II) nitrate trihydrate (0.01 M in 20 ml) was added slowly to the Schiff base solution with stirring followed by an aqueous solution of sodium carbonate (0.01 M in 20 ml). The mixture was stirred magnetically at 60°C for one hr and then cooled to room temperature. The separated green precipitates were suction filtered washed with ethanol and dried under vacuum. It was recrystallised from benzene and dried under vacuum (Yield 50%).

I

II

*Cu*(pyrrole-2-amino-2-methylpropanol) was prepared by following a similar procedure as described above. The complex was recrystallised from chloroform. (Yield 50%).

The microanalyses were done at the University of Bombay. The analytical data are given in Table I. The magnetic susceptibility measurements

were done by the Gouy method. Diamagnetic corrections of the metal and ligand atoms were calculated using a standard source<sup>5</sup>. Electronic spectra were recorded in chloroform with a Beckman DK2 recording spectrophotometer using 10 mm matched quartz cells. IR spectra were recorded in KBr pellets on a Perkin Elmer Model 21 instrument. The molecular weights were determined in chloroform at 37°C using a Hewlett-Packard Mechrolab Model 301A vapour pressure osmometer calibrated with benzil.

## RESULTS AND DISCUSSION

The infrared spectra of the complexes do not exhibit the  $\nu(\text{OH})$  stretching vibration indicating the ligand coordination, dibasic character of the ligands and the absence of coordinated water in the complexes. The osmometric molecular weight measurements in chloroform indicate that the copper (II) complex of I is tetrameric (Found : 840, Calcd. 854), and of II is dimeric (Found : 410, Calcd. 455). Apparently the steric factor associated with the presence of two methyl groups in the ligand II is preventing the formation of tetrameric copper (II) complex. The electronic spectra in chloroform of copper (II) complexes of I and II exhibit a broad absorption band at 15950 and 17030  $\text{cm}^{-1}$  respectively. This difference in band position may be attributed to the presence of different structures in these complexes<sup>6,7</sup>.

The magnetic susceptibilities and magnetic moments of the complexes at several temperatures are presented in Table II. The magnetic moments of the copper (II) complex of I increase as the temperature is lowered. On the other hand, the magnetic moments of the copper (II) complex of II decrease with lowering of temperature. Approximating the magnetic properties using the Bleaney and Bowers equation<sup>8</sup> gave positive  $J$  value ( $J = +35 \text{ cm}^{-1}$ ) for the copper (II) complex of I and negative  $J$  value ( $J = -133 \text{ cm}^{-1}$ ) for the copper (II) complex of II. Thus the magnetic data indicate that the copper (II) complexes of I and II are ferromagnetic and antiferromagnetic,

<sup>a</sup> Magnetic moment was calculated using the Curie equation:

$$\mu_{\text{eff}} = 2.84 (\chi_{\text{M}}^{\text{corr}} T)^{\frac{1}{2}} \text{ BM.}$$

<sup>b</sup> T.I.P. =  $50 \times 10^{-6}$  cgs units.<sup>c</sup>  $g = 2.05$  was used.

respectively<sup>1,4,9,10</sup>. This difference in magnetic behaviour in these two complexes may be related to the presence of different structures in these complexes—One a tetramer and the other, a dimer. As the ligands I and II both form five membered chelate rings around copper (II) in aminoalcohol part of the molecules, we believe this significant difference in magnetic behaviour is due to the steric hindrance of the two methyl groups which prevent the formation of tetramer in copper (II) complex of II. On the basis of X-ray structure determination of known copper (II) complexes of tridentate dibasic Schiff bases with comparable magnetic properties, we propose a square planar structure for the dimeric, antiferromagnetic copper (II) complex of II and a distorted trigonal bipyramidal arrangement for the tetrameric, ferromagnetic copper (II) complex of I<sup>167</sup>.

It is interesting to note that the copper (II) complex of pyrrole-2-aldehyde-propanolamine is dimeric with square planar arrangement around each copper (II) and the complex is involved in the antiferromagnetic spin-spin coupling<sup>6</sup>. This ligand forms a six membered chelate ring around copper (II) in aminoalcohol part of the molecule. When the size of the chelate ring is five membered in the copper (II) complex of the ligand I one gets a ferromagnetic copper (II) compound. We do not

see this chelate ring effect in the copper (II) complex of the ligand II due to the steric hindrance as described earlier.

## PHOTOSYNTHETIC CARBOXYLASES IN WILD AND CULTIVATED WHEATS

RENU KHANNA AND S. K. SINHA

Water Technology Centre, Indian Agricultural Research Institute, New Delhi 110012

IN recent years physiological aspects such as photosynthesis rates, nitrate reductase activity, chlorophyll and nitrogen content have been examined in primitive and cultivated wheats (Evans and Dunstone, 1970; Khan and Tsunoda, 1970, Sinha and Khanna, 1972. Sinha *et al.*, 1974). These studies reveal that the primitive wheats are characterized by higher photosynthesis rates (Evans and Dunstone, 1970, Khan and Tsunoda, 1970). We report the variation in the activities of RuDP carboxylase (Ribulose 1-5 diphosphate carboxylase) and PEP carboxylase (phosphoenol pyruvate carboxylase) in diploid, tetraploid and hexaploid wheats during growth and development in flag leaf and ear parts. These were the same genotypes which we examined for variation in photophosphorylation (Sinha and Khanna, 1972).

Seeds of a diploid *Triticum monococcum* L., a tetraploid *T. durum* Desf. and a hexaploid *T. aestivum* Villcv. Kalyansona were sown in pots and plants were raised as described earlier (Sinha and Khanna, 1972). The activities of RuDP carboxylase and PEP carboxylase were determined after the emergence of flag leaf. These enzymes were assayed according to the methods described by Bjorkman and Gauhl (1969) and Khanna and Sinha (1972). Photosynthetic carboxylase activity has been shown to be positively correlated with photosynthesis rate by Neals, Treharne and Wareing (1971) and Nagy *et al.* (1972). Results are expressed on fresh weight of leaves, awns, and glumes.

RuDP carboxylase activity in the flag leaf of diploid and tetraploid wheat was more than that in hexaploid before anthesis occurred (Table I). At anthesis, the activity of this enzyme was enhanced by 50% in tetraploid and about three times in hexaploid wheat. Earlier results had shown enhanced CO<sub>2</sub> fixation and O<sub>2</sub> evolution at anthesis in Kalyansona, a hexaploid type (Sinha unpublished). When the grain development started the diploid still maintained the same enzyme activity but it declined in the other two genotypes as compared to the anthesis stage.

The activity of PEP carboxylase was very low as compared to RuDP carboxylase. There was decline in the activity of this enzyme following anthesis in tetraploid and hexaploid but was less affected in diploid.

Awns of wheat and barley are known to contribute photosynthetically towards grain yield (Yoshida, 1972) RuDP carboxylase activity of awns was higher in diploid and tetraploid at preanthesis (Table II). At anthesis the enzyme activity in awns increased in tetraploid and hexaploid but was unaffected in diploid. In glumes which are even more closer to grains the activity of RuDP carboxylase was almost the same in all the types before anthesis (Table II). At anthesis maximum stimulation in the activity of this enzyme occurred in the tetraploid, although slight increase was observed in diploid and hexaploid types. Very low PEP (0.09–0.64  $\mu$  moles CO<sub>2</sub> fixed g<sup>-1</sup> fw min<sup>-1</sup>) carboxylase activity was observed in the awns and glumes at all the three stages.

It is known that the ear size, grain number and grain weight increases from diploid to hexaploid leading to greater 'sink' capacity (Evans and Dunstone, 1970). Earlier studies were confined to seedlings wherein higher photosynthesis rates were obtained in primitive types (Evans and Dunstone, 1970; Khan and Tsunoda, 1970). The creation of 'sink' seems to have a profound effect on the photosynthetic potential of wheat leaves and other photosynthetically active parts. It would be seen from Table I that the flag leaf of hexaploid had poor rates before anthesis but reached maximum at anthesis. A similar observation was made in respect of photophosphorylation (Sinha and Khanna, 1972). However, the glumes and awns of tetraploid type had higher amount of RuDP carboxylase. Our recent studies indicate a large amount of photosynthate contribution by awns and glumes to the developing grains of wheat (Khanna and Sinha, 1973).

The present study indicates that the primitive wheats do not have higher photosynthesis rates at all stages of development as compared to the advanced types. The photosynthetic potential

changes with the stage of development and the availability of 'sink'. Thus comparisons of physiological traits may have only a limited significance in determining evolutionary relationships.

## CURRENT SCIENCE

Fortnightly Journal of Research

Issued on the 5th and 20th of each month

### IMPORTANT NOTICE TO SUBSCRIBERS OF THE JOURNAL

As you are aware CURRENT SCIENCE has been coming out regularly on the due dates as above with the kind co-operation of you all.

On account of the sharp increase in the cost of quality paper used for the Journal, increase in rates of block making materials, increase in postal rates and the increase in the establishment charges it has become impossible for the Association to issue the Journal, unless the subscription rates are put up.

The Working Committee of the Association has reluctantly decided at its last meeting, to enhance the subscription of CURRENT SCIENCE with effect from 1st January 1975 for institutions :

India Rs. 84/- Foreign Rs. 150.00 \$ 20.00 or £ 8.0.0

The subscription rates for individual subscribers however will remain the same as now.

The continued co-operation of our subscribers is requested.

## LETTERS TO THE EDITOR

### EFFECT OF ANNEALING ON THE CATALYTIC ACTIVITY OF COPPER\*

BHAKTA AND TAYLOR<sup>1</sup> have shown that gold catalyst, on annealing *in vacuo* in the temperature range of 200° to 400° C followed by quenching at liquid air temperature, acquired excess activity (towards the dehydrogenation of formic acid) which decayed out at a lower anneal temperature. The present investigation was undertaken to ascertain whether copper would also show a similar effect upon annealing in air for one hour at 250° to 550° C followed by either (a) quenching in water at 25° C, or (b) slow cooling in a furnace. The results revealed some unexpected interesting features. Square pieces (3.0 cm × 3.0 cm) of copper foils (99.9% purity, B.D.H.) from separate lots I, II and III, of mean thickness 0.10 mm, 0.12 mm and 0.13 mm, respectively, were used; the gm. equiv. of hydrogen peroxide (0.25 N) decomposed per unit surface area of the foil during the initial 10 min. of the reaction at 69.5° C at a stirrer speed of 200 rpm was taken as a measure of the activity,  $a$ , of the foil.

As the activity of the unannealed foils were found to be nearly proportional to the reciprocals of their thickness, mapping of the annealing data of the three foils on a single scale based on  $a_0$  ( $1.58 \times 10^{-4}$  gm. equiv. cm.<sup>-2</sup>, the activity of the unannealed foil I) was possible. (Fig. 1).

FIG. 1

This investigation has revealed that

A. the activities of the foils I, II and III.

- (i) remained, apparently, constant at their respective unannealed values (i.e.,  $a_0$ ,  $0.85 a_0$ ,  $0.80 a_0$ , respectively) upto  $T_A \sim 300^\circ \text{C}$ .

- (ii) attained the same minimum residual activity ( $0.5 a_0$  approximately) in the same  $T_A$  range of  $330^\circ \text{C}$  to  $380^\circ \text{C}$ .
- (iii) showed similar trend of activity increase (following the minima) to reach once again values nearly equal to their respective unannealed ones, at about the same temperature range ( $380^\circ \text{C}$  to  $420^\circ \text{C}$ ) and remained practically constant at  $T_A > 420^\circ \text{C}$ .
- (iv) showed the same pattern of behaviour, viz., (i), (ii) and (iii) when the foils were furnace-cooled (instead of quenched) after annealing at  $T_A$  range  $250^\circ \text{C}$  to  $550^\circ \text{C}$ .

and

B. the Vickers microhardness of foil II remained unchanged upto  $T_A \sim 420^\circ \text{C}$ , thereafter it decreased to a final constant value (70% of the initial value) at  $T_A \sim 480^\circ \text{C}$ .

In passing, it can be noted that the onset of 'softening' of a foil began at about  $420^\circ \text{C}$  at which it attained the maximum activity. At the present moment it is not possible to say if this is a mere coincidence.

The activity decay in the  $T_A$  range  $300^\circ \text{C}$  to  $380^\circ \text{C}$  follows a pattern similar to that observed by Eley and MacMahon<sup>2</sup> and Uhara *et al.*<sup>3</sup>. The present investigation succeeds in clearly delineating the complete picture of the changes in the activity of the foils in the  $T_A$  range of  $250^\circ \text{C}$  to  $550^\circ \text{C}$ .

It seems likely that the free surface of the copper foil is itself active accounting for the unannealed activity ( $0.5 a_0$ ). The activity of the foil in excess of  $0.5 a_0$  may be attributed to the surface terminations of dislocations in accordance with the views of Cratty and Granato<sup>4</sup>; the annealing characteristics of its hardness are also consistent with these views. These dislocations are, perhaps, introduced in the foils when they were cold-rolled (during manufacture); as the thinness of a foil is, presumably, proportional to the amount of cold-work performed and, consequently, to the number of dislocations introduced, the reason for the observed dependence of the activity of a foil on the reciprocal of its thickness, becomes clear.

The rise in the activity following the minimum is, however, not easy to interpret. There is, undoubtedly, visible roughening of the surface of the foil after annealing at  $T_A > 380^\circ \text{C}$ . But this alone is not sufficient to account for the observed increase in the activity; nor can this increase be attributed

to the streams caused by quenching. As the quenched foil did not behave differently from the furnace-cooled one. As every foil was first immersed in 1*N*  $H_2SO_4$  for 3 to 4 min. (until it regained its shine) before it was used as a catalyst, the probability that the oxide film on its surface might be responsible for the increase in activity is small. Incidentally, it is worth noting that silver catalyst, too, exhibited similar increase in activity<sup>2</sup> when hydrogen peroxide decomposition and ethanol oxidation (and not formic acid dehydrogenation) were the probe reactions. This observation may be of significance to the understanding of the mechanism of metal catalysed reactions.

### ELECTRONIC SPECTRAL AND THERMAL STUDIES OF Ce(III), Pr(III) AND Nd(III) PICRAMATES

SOME inner transition metal picramates, viz. lanthanum, cerium, praseodymium, neodymium, samarium, gadolinium, dysprosium and holmium picramates, were prepared recently by us and their stoichiometry established by elemental analysis, amperometric, conductometric and potentiometric

analysis<sup>1</sup>. We also suggested  $-H_2N \rightarrow Ln$  coordination ( $Ln$  = rare earth ion) in metal picramates on the basis of i.r. spectral studies. The present communication reports the electronic spectral and thermal studies of cerium, praseodymium and neodymium picramates. The nature of the complexes has also been studied by measurements of electrical conductance.

The conductance and electronic spectra of the complexes were made as reported in the earlier communication<sup>2</sup>.

The low molar conductivity of the complexes in dimethylformamide showed that these complexes are non-electrolytes. The spectral data of praseodymium and neodymium picramates in ethanol are summarised in Table I, and for comparison, data for aqueous salt solutions are also given.

The spectral behaviour of lanthanides is fundamentally different from that of *d*-block elements. The basic reasons for the differences lies in the fact that the electrons responsible for magnetic spectral properties of lanthanide ions of 4*f* electron and 4*f* orbitals are effectively shielded from interaction with external forces by the overlapping of 5*s*<sup>2</sup> and 5*p*<sup>6</sup> shells. The bands may be assigned to the transitions in which an *f* electron is excited to an outer *d*, *s* or *p* orbital<sup>3</sup> and the spectra have been assigned to 4*f*–5*d* transitions<sup>4</sup>. The electronic spectra of the cerium picramate show five bands appearing at 21735 (vw), 23250 (vw), 31755, 44455 and 47660  $cm^{-1}$ . The first three bands may be due to Laporte-allowed 4*f*–5*d* transitions.

It is evident from Table I that the shifts in the spectra of praseodymium and neodymium picramates are towards lower wave numbers relative to the aquo ions. There are small differences in frequencies or molar absorption except that the hypersensitivity transition  $^4I_{9/2} \rightarrow ^4G_{7/2}$  in the neodymium picramate which increases in intensity from  $\epsilon = 6.25$  in the salt to  $\epsilon = 17.50$  in the com-

\* Values in parentheses show the nephelauxetic effect (1– $\beta$ ).

plex. Thus it is clear that 4f orbitals do not participate much in bonding; if they did, vibronic coupling would lead to marked changes in intensity, position, and sharpness of the  $f-f$  transitions. Four bands have been observed in the electronic spectra of praseodymium picramate which are due to transition from the ground level  $^3H_4$  to the excited J levels of 4f<sup>2</sup> configuration respectively. The red shift or nephelauxetic effect which is regarded as a measure of the covalency of the coordination bond was calculated for the rare earth complexes by Jørgensen *et al.*<sup>5</sup>, using the relation

$$1-\beta = (\bar{\nu}_{\text{aqu}} - \bar{\nu}_{\text{complex}}) / \bar{\nu}_{\text{aqu}}$$

(where  $\bar{\nu}$  is the wave number of absorption band of rare earth ion) and assuming that each J level of a 4f<sup>n</sup> configuration is linearly dependent on the radial integrals. On the basis of this assumption,  $\Delta\bar{\nu}/\bar{\nu}_{\text{aqu}}$  of all bands of the same rare earth complex should be similar. However, our earlier observations<sup>3</sup> as well as the present results (Table I) indicate that the  $\Delta\bar{\nu}/\bar{\nu}_{\text{aqu}}$  values for different J levels of a rare earth complex differ from each other considerably.

**Thermal Study.**—Thermogravimetric analysis of the samples was done by the method described by Agrawal *et al.*<sup>8</sup>. In the case of Ce picramate one water molecule is lost around 90°C and the second water molecule around 128°C. On the other hand, in the case of Pr and Nd picramates both the water molecules are lost around 130°C. Ce, Pr and Nd picramates decompose into the stable oxides (Ln<sub>2</sub>O<sub>3</sub>) at 450°, 650° and 700°C respectively; the increase in the thermal stability is perhaps due to a decrease in the O-Ln bond on account of lanthanide contraction.

# ε-CAPROLACTAMS FROM 4-ALKYL-, 4-DIHALO- AND 4-TRIHALO-ALKYL-2, 5-CYCLOHEXADIENONES

In our earlier publications<sup>1</sup> we have reported some of the interesting reactions of 4-alkyl-, 4-dihalo- and 4-trihalo-alkyl-2,5-cyclohexadienones. We report here the preparation of three caprolactam derivatives from these dienones. The latter were prepared from *p*-alkyl phenols by reaction with chloroform or carbon tetrachloride as described in literature and were catalytically reduced in alcohol solution with 5% Pd/charcoal to yield the corresponding cyclohexanone derivatives. The oximes of the latter, prepared as usual, when subjected to a Beckmann rearrangement in the presence of conc. sulphuric acid or PCl<sub>5</sub> afforded the lactams as colourless crystalline solids from benzene-pet. ether in yields ranging from 30–50% as in the case of III d. The rearrangement of the oxime IIc takes place only with PCl<sub>5</sub>. Sulphuric acid however gives a tarry mass.

I. R = H, R<sub>1</sub> = CHCl<sub>2</sub> :

(a) m.p. 54°<sup>2a</sup> ; (b) m.p. 47°<sup>2b</sup>  
(c) m.p. 132–34° ; (d) m.p. 152–54°.

II. R = H, R<sub>1</sub> = CCl<sub>3</sub> :

(a) m.p. 104°<sup>3a</sup> ; (b) m.p. 116°<sup>3b</sup> ;  
(c) m.p. 170–71° ; (d) m.p. 160–61°.

III. R = CH<sub>3</sub>; R<sub>1</sub> = CHCl<sub>2</sub> :

(a) m.p. 102°<sup>2a</sup> ; (b) m.p. 87° ;  
(c) m.p. 157° ; (d) m.p. 172–74°.

In the case of the oximes there is the possibility of syn- and anti-isomers being formed but in all cases only one product could be isolated. Similarly, in the case of compounds III b–III d, the possibility of *cis-trans* isomers also exists but here again only one compound could be obtained. From the spectral data collected by us it is not possible to assign any definite configuration to the methyl group in these compounds.

The i.r. spectrum (KBr) of a typical caprolactam (Id) showed bands at 3200, 1660 and 1300 cm<sup>-1</sup> corresponding to an amide (secondary) grouping.

The n.m.r. spectrum (CDCl<sub>3</sub>) of III d showed the methyl protons at C<sub>1</sub> as a singlet at 1.3 δ while a doublet around 0.9–1.1 δ for three protons was assigned to the methyl protons at C<sub>2</sub>. The complex multiplet at 1.5–3.9 δ for seven protons corresponded to the six methylene and one methine proton at C<sub>2</sub>. The singlet for one proton at 5.65 δ was

attributed to the proton of the dichloromethyl group at  $C_1$ . The NH proton was obtained as a broad singlet at 7.12  $\delta$ .

All the compounds gave satisfactory analysis for C, H and N.

### SUBSTITUENT EFFECT OF THE $CF_3$ GROUP IN AROMATICS

THE effect of the  $CF_3$  group on the electron distribution of the phenyl part has been discussed by many workers<sup>1-6</sup>. Different mechanisms such as fluoride type no bond resonance, hyperconjugation and similar other mechanisms have been suggested to explain the strong electron withdrawing effect of the  $CF_3$  group.

Spectra of isomeric trifluorotoluidines  $CF_3C_6H_4NH_2$  have been studied in detail in solution as well as in the vapor phase. The solution spectra are shown in Fig. 1. On the basis of a large

Fig. 1

amount of data on substituted anilines, Forbes and Leckie<sup>7</sup> have drawn some conclusions regarding the effect on the ultraviolet spectrum of aniline as a function of the nature of the substituent. Present results are discussed in the light of these as also general considerations of substituent effect.

The two bands generally observed in the spectra of substituted anilines in the region above 200  $m\mu$

are the usual B and C bands, the former being around 240  $m\mu$  and the latter around 295  $m\mu$ .

It has generally been accepted that the B band has a large contribution of intramolecular charge transfer state. The effect in para substituted anilines when the other substituent is an electron withdrawing, is a large bathochromic shift of the aniline B band and the C band remaining more or less in the same position. In some cases two bands merge giving only a broad single band. In the case of ortho and meta isomers, for acceptor substituents, quite often, two B bands are observed and the C band shows a large bathochromic shift.

In  $CF_3$  substituted anilines, since  $CF_3$  is an acceptor group, the spectral changes in general follow the above pattern, but there are some pertinent differences. First, the shift of the C band in meta and para isomers is much less than for other electron accepting substituents like formyl, acetyl with delocalised  $\pi$  orbitals. Secondly the B band does not show a splitting in ortho and meta isomers as in other cases. This shows that the electron withdrawal mechanism of  $CF_3$  group is different from the usual acceptors like formyl.

It is known that the spectral effects in case of unsaturated acceptors like formyl are principally due to  $\pi$  electron induction. Splitting of the B band in ortho and meta substitutions is due to the separation of the benzenoid B band and the aniline charge transfer band resulting from the pronounced lowering of the latter. The shift of the B band in para and of C in ortho and meta are also due to the some electronic effect. Thus the electron withdrawal mechanism of the  $CF_3$  group does not seem to be due to  $\pi$  induction but due to field effect. It is interesting to note that a similar idea has been put forward by Streitwieser and Holtz to account for the differences in reactivity.

# A MICRO SUBLIMATION STEP IN THE UV SPECTROPHOTOMETRIC DETERMINATION OF DIAZINON

THE microdetermination of diazinon<sup>1-3</sup> through 2-isopropyl-6-methyl-4-pyrimidinol is tedious; further the presence of animal and vegetable co-extractives complicate the analysis. In this communication a micro sublimation step is described for the purification of the pyrimidinol before UV determination.

2-isopropyl-6-methyl-4-pyrimidinol sublimes to white crystalline needles. The sublimation of the pyrimidinol is carried out by heating at  $115 \pm 1^\circ \text{C}$  for 10 minutes and is thus purified from co-extractives which in effect do not volatalise at this temperature.

The sublimation assembly (Fig. 1) consists of a metallic hot air-bath top covered with an asbestos sheet.

FIG. 1. Diagram showing the sublimation assembly.

An unsputted specimen tube fits the central hole of the asbestos cover, through another hole passes a thermometer. The receiver is another unsputted specimen tube of a slightly larger diameter. The bath may be heated either electrically or by flame at the rate of about  $10^\circ \text{C}$  per minute.

The contaminated pyrimidinol requiring purification is taken in the specimen tube, and the sublimation carried out at  $115 \pm 10^\circ \text{C}$  for 10 minutes and then the apparatus is allowed to cool to the ambient temperature. The sublimate is dissolved in 95% V/V ethanol and absorbance measures at 272 nm. The quantity of diazinon is then determined from a calibration curve prepared from purified pyrimidinol. One mg of pyrimidinol is equivalent to 1.657 mg of diazinon. The calibration curve obeys Beer's Law over the range of 0-80 ppm of pyrimidinol and the molar extinction coefficient is 4864.

For recovery studies known quantities of the pyrimidinol were spiked with about 500 fold excess

of tissue extractive and the recovery by sublimation determined. Recovery of the pyrimidinol by the proposed method was satisfactory and reproducible and was found to be 99.25% with a standard deviation of  $\pm 0.75\%$  upto  $100 \mu\text{g}$  level. Sublimation of quantities greater than  $100 \mu\text{g}$  results in substantial loss of the pyrimidinol and is therefore not recommended. It was found that a slight variation in the sublimation assembly did not significantly affect the recovery.

This purification step by micro sublimation should find an extensive application in the determination of diazinon in matrices such as animal tissue, vegetable matter, etc., giving copious co-extractives.

The authors thank F. V. Arul, the Director, P. Chandra Sekharan and Dr. Pichammal Visvanath, the Additional Directors, for encouragement.

## DISTRIBUTIONAL PATTERN OF THYROTROPHS IN THE PITUITARY OF HETEROPNEUSTES FOSSILIS (BLOCH.) BASED ON RADIOTHYROIDECTOMY

ALTHOUGH the pituitary of teleosts has been extensively studied<sup>6,1,7,8,4</sup> lack of agreement about the function of the various pituitary cell types is obvious. It is largely due to the fact that experimental allocation of function to the cells has been attempted systematically only in a few species<sup>1</sup>. In the teleosts the distributional pattern of the thyrotrophs greatly vary among different species. In some they are situated in the proximal pars distalis<sup>2</sup>, whereas in others they are in the rostral pars distalis<sup>3</sup> or even between the two zones<sup>5</sup>.

In the present investigation 10 *H. fossilis* were given  $250 \mu\text{Ci}$  of I-131 in two instalments at an interval of six months and sacrificed after the completion of a full year. The pituitary was fixed in Bouin's fluid containing 5 gm of Mercuric Chloride; sections were cut at  $5 \mu$  thick and stained in combination of PAS and lead haematoxylin (PbH), aldehyde fuchsin (AF) with Halmi's fastgreen-Chromotrope 2R-Orange G and Mallory's triple stain. Thyroid was fixed in Bouin's fluid, stained in PAS and Ehrlich haematoxylin and autoradiographs were prepared using NTB 3 Kodak emulsion.

In only one fish remnants of the thyroid was present in the form of 3 or 4 scattered micro-follicle which gave positive autoradiograph (Fig. 4). In the others as no viable thyroid tissue was present autoradiographs were negative. In the partial thyroidectomised fishes as the thyroid is in the form of microfollicle autoradiograph is very small when compared to the controls (Fig. 5). Both in partial and total radiothyroidectomised fishes the pituitary thyrotrophs exhibited extensive compensatory hypertrophy. They measure  $14\mu$  in diameter in comparison to control which measure only  $7\mu$  (Figs. 1 and 3). The activated nuclei is found with prominent nucleoli. Several of them have large vacuoles in their cytoplasm (Figs. 1, 2).

Figs. 1-5. Figs. 1, 2. Arrows show hypertrophied thyrotrophs in the radiothyroidectomised fish,  $\times 800$ . Fig. 3. Arrows show thyrotrophs in a normal fish,  $\times 800$ . Fig. 4. Autoradiograph of the thyroid in a partially thyroidectomised fish,  $\times 80$ . Fig. 5. Autoradiograph of three thyroid follicles in a normal fish  $\times 80$ .

These hypertrophied cells sometimes lack a distinct cell boundary and groups of them look like a syncytium. In the control specimens it is difficult to differentiate the thyrotrophs from the gonadotrophs as both were stainable with PAS, AF, aniline blue and fastgreen. In this species the thyrotrophs are localised in the middle of the proximal pars distalis flanked by gonadotrophs on either side. The acidophilic somatotrophs are distributed throughout the proximal pars distalis.

#### EFFECT OF A COPPER INTRA-UTERINE CONTRACEPTIVE DEVICE ON SUB-CELLULAR DISTRIBUTION AND CONCENTRATION OF COPPER IN THE RAT UTERUS

COPPER containing intrauterine contraceptive device (Cu-IUD) has been reported to have better contraceptive efficacy and minimum side-effects than the polyethylene IUDs. The primary mode of action of copper has been attributed to its effect on endometrium and alteration of uterine fluid milieu both in animals and woman<sup>1</sup>. The catalase enzyme activity in the endometrium of rat is reported to be stimulated by Cu-IUD<sup>2</sup>. The presence of copper in cervical mucus inhibits sperm penetration<sup>3</sup>. There is non-uniform dissolution of copper ions from wire and even flakes of copper are shed from the wire<sup>4</sup> but the overall release rate of copper from device is  $10.3\text{ mg/year}^5$  and its concentration is significantly higher in the late secretory phase in woman<sup>6</sup>. It is pertinent to mention that copper content of liver, lungs, etc., remains unaltered after Cu-IUD signifying its local effect<sup>4</sup>. The subcellular localisation of copper in the uterus is still unknown.

Accordingly, the present investigation deals with the subcellular distribution of copper in rat uterus fitted with a copper IUD.

Colony bred adult female albino rats (150-200 gm) of the Institute with regular estrous cycle were used in this investigation. A piece of clean, soft, 100% copper wire (0.2 mm diameter) was fitted through the lumen of one uterine horn irrespective of the stage of the cycle by methods described previously<sup>2</sup>. The contralateral horn was sham operated by passing the suture needle through the uterine lumen and served as control. Surgery was carried out under aseptic precautions.

The animals were sacrificed 15 day after Cu-IUD insertion or sham operation during the estrus phase of the cycle. The copper-bearing and control uterine horns were carefully dissected out, pressed between filter papers to remove the luminal fluid and weighed to the nearest 0.2 mg on a Roller-Smith balance. Copper was estimated by the technique of Hubbard and Spettel<sup>7</sup> and polarographic estimations were done by the method described earlier<sup>8</sup>.

TABLE I

The uptake of copper ions ( $\mu\text{g/gm}$  wet-weight) by subcellular fraction of rat uterus

| Fractions    | Uterus          |                 |
|--------------|-----------------|-----------------|
|              | Control horn    | Cu-IUD horn     |
| Nuclear      | $1.57 \pm 0.14$ | $2.88 \pm 0.17$ |
| Mitochondria | $1.33 \pm 0.14$ | $1.30 \pm 0.10$ |
| Microsomes   | $0.65 \pm 0.11$ | $0.67 \pm 0.65$ |
| Supernatant  | $2.43 \pm 0.17$ | $4.00 \pm 0.12$ |
| Whole tissue | $6.43 \pm 0.16$ | $8.60 \pm 0.29$ |

Data is based on 6 estimations of each fraction.

It will be evident from the results presented in Table I that the concentration of copper was highest in both the horns in supernatant followed by nuclear, mitochondrial and microsomal fractions in a diminishing order. In the Cu-IUD bearing uterine horn, there was a significant increase in copper in nuclear and supernatant fractions ( $P < 0.01$ ) while its level remained virtually unaltered in mitochondrial and microsomal fractions. In the whole uterine tissue, also copper was significantly accumulated in Cu-IUD horn ( $P < 0.01$ ).

Copper is a versatile catalyst and participates in a number of enzyme reactions under normal physiological concentrations. A significant increase in the copper content of Cu-IUD bearing uterine horn appears to create a pharmacological condition and inhibits or blocks copper dependant enzymes, thereby making the endometrium hostile to reception of eggs. It is reported that continuous liberation of metal ions in the uterine lumen is necessary for their sustained contraception action<sup>9</sup>. Histochemically, copper has been demonstrated in the endometrium of women during the secretory phase<sup>10</sup>.

Thus the present study reveals that copper gets accumulated in the uterus and apparently alters its receptivity to eggs.

Studies are in progress to determine the release rate of copper in the uterine tissue and fluid.

This investigation was supported by a grant from the Ministry of Health and Family Planning, Government of India. Thanks are due to Dr. M. L. Dhar for his keen interest in this study and to Shri R. P. Sinha and Miss Shobha Srivastava for technical assistance.

# OCCURRENCE OF STREPTOMYCIN RESISTANT AND DEPENDENT MUTATIONS IN *RHIZOBIUM LUPINI* UNDER THE INFLUENCE OF NITROUS ACID

RESISTANCE, dependence and sensitivity to streptomycin are well known in bacteria. Newcombe and Hawirko<sup>1</sup> isolated streptomycin dependent mutants of *Escherichia coli* in the presence of streptomycin. These mutants would not grow if streptomycin was not supplied to the medium. Balassa and Gabor<sup>2,3</sup> studied transformation using a streptomycin dependent strain of *Rhizobium lupini* which had been obtained as a single step spontaneous mutant. A streptomycin dependent strain was isolated by Mishra and Ravin<sup>4</sup> from a streptomycin resistant population of *Diplococcus pneumoniae*. In the present report isolation of a streptomycin dependent strain by the treatment of the streptomycin sensitive strain of *Rhizobium lupini* with nitrous acid is communicated.

A strain of *Rhizobium lupini* (H-13-3) obtained from the Hungarian Academy of Science,

budapest, Hungary, was used. Strain  $SM_1S_{10}$  was obtained as a spontaneous streptomycin resistant mutant from this strain. Strain  $NSD_1$  was a streptomycin dependent strain obtained as a result of nitrous acid treatment of sensitive strain H-13-3.

**Mutagenic treatment.**—Freshly growing cell suspension of *Rhizobium lupini* was diluted ten times in liquid complete medium as described by Balassa<sup>2</sup> and which also contained 1 ml of vitamin mixture, 2 ml of RNA hydrolysate and 1 ml of DNA hydrolysate per litre of medium and incubated overnight at 30° C. After washing with normal saline and resuspending in the same volume of normal saline the cells were treated with nitrous acid at a concentration of 0.017 M at pH 4.5 for 0 to 120 seconds. The reactions were terminated by adding 1 ml of the treated sample to 99 ml of complete liquid medium at pH 7.0 and incubated for 18 hours at 30° C. Platings were done on plain CM-agar and CM-agar containing streptomycin, immediately after treatment as well as after post treatment incubation. Colonies arising on antibiotic plates were further tested for their ability of resisting higher concentrations of the antibiotic.

From Fig. 1, it is evident that the percentage of survival decreases exponentially with the increase

FIG. 1. Effect of nitrous acid on survival and mutation in *R. lupini* (strain H-13-3).

of time of treatment with nitrous acid whereas, the percentage of streptomycin resistant mutation did not show such type of relationship. In the case of streptomycin resistant mutation, the highest rate of mutation occurred at 60 seconds of nitrous acid treatment followed by post incubation after which the mutation rate decreased. It was concluded (Fig. 1) that streptomycin resistant mutations were highest when the killing was between 5 to 10%.

Only one streptomycin dependent strain designated as  $NSD_1$  was obtained at 60 seconds of treatment with nitrous acid followed by post-incubation for the expression of mutation, and all other colonies were streptomycin resistant.

FIG. 2. Growth pattern of streptomycin resistant strain  $SM_1S_{10}$  at different concentrations of streptomycin.

**Growth pattern of streptomycin dependent strain as compared with streptomycin resistant and sensitive strains.**—For the study of the growth pattern of three strains streptomycin sensitive H-13-3, streptomycin resistant  $SM_1S_{10}$  and streptomycin dependent  $NSD_1$ , freshly growing cells in exponential phase were washed twice in normal saline and resuspended in liquid complete medium in a number of 50 ml Erlenmeyer flasks to which different concentrations of streptomycin were added.

One set for each strain was left without the addition of the antibiotic. Platings were done after 0, 2, 4 and 6 hours of incubation at 30°C and colonies were counted after 48 hours of incubation.

FIG. 3. Growth pattern of streptomycin dependent strain NSD<sub>1</sub> at different concentrations of streptomycin.

The complete inhibition of sensitive cell was more pronounced at higher concentration than at lower concentrations. Streptomycin sensitive strain H-13-3 showed killing effect in presence of only 10 µg/ml streptomycin and with higher concentrations none of the cells survived. Streptomycin dependent strain NSD<sub>1</sub> had difficulty in surviving in the absence of streptomycin (Fig. 3) proving thereby, that streptomycin was essential for its growth but strain H-13-3 and SM<sub>1</sub>S<sub>10</sub> had no such difficulty in the absence of streptomycin (Fig. 2). It has been established by Spotts and Stanier<sup>6</sup> that streptomycin causes some alterations in the structure of the ribosomes in such a manner that the dependent mutation hampers their ability to combine with certain types of messenger RNA. This may be repaired by the addition of streptomycin. The sensitive cells have great affinity for streptomycin which makes the ribosomes incapable of combining with messenger

RNA but the ribosomes of resistant cells have no such affinity, being unaffected by streptomycin. Both resistant and dependent strains showed increase in growth in the medium containing low concentrations of streptomycin but decrease was observed in the case of high concentrations thereby showing that most probably, in this case, the ribosomes were adapted only for the lower concentrations of the antibiotic and that the protein synthesis was hampered at higher concentrations of the antibiotic.

#### A NEW RECORD FOR *CARIDINA BRACHYDACTYLA PENINSULARIS* KEMP, 1918 (DECAPODA, CARIDEA, ATYIDAE) FROM INDIA

THE present note reports the subspecies *Caridina brachydactyla peninsularis* Kemp for the first time from continental Asia beyond the Malayan peninsula. The subspecies is quite common in a perennial pond and neighbouring semi-permanent pools on the outskirts of Guntur (16°18' N and 80°29' E; MSL + 31.88 m) in Andhra Pradesh, India. The rain-fed pond also receives some water from river Krishna through an irrigation canal.

A random sample of forty-five specimens from material collected over the period March 1973 to July 1974 was utilised for biometric studies. The data were compared with those of Kemp<sup>1</sup>, as well as those of the syntypes in the British Museum (kindly sent by Dr. R. W. Ingle). There is general concurrence of the data.

The largest specimen examined is a berried female of TL 23.5 mm, CL 5.0 mm, RL 5.0 mm; the corresponding data for the largest male are 22.0, 4.0 and 4.5 mm. The rostrum (Fig. 1), which is of diagnostic importance, extends beyond the antennular peduncle and in some specimens, even a little beyond the antennal scale; its dorsal margin along its entire length is provided with a series of 31 to 46 teeth (usually 34-38), of which

2 to 4 lie on the carapace; the dorsal teeth are moveable, and a pair of setae are set between successive teeth. The ventral margin of the rostrum bears 6 to 15 teeth (usually 9-11); the distal part of the ventral border is unarmed: the ventral teeth are immovable, laterally compressed and without any setae between them.

FIG. 1. *Caridina brachydactyla peninsularis* Kemp, 1918; rostrum (CL = 3.5 mm).

Body in general translucent; while minute orange, maroon and green chromatophores are scattered over the entire body, they are closer together along the posterior borders of the somites, on the telson and on uropods. Antennular peduncles and eye-stalks have larger green and deep maroon chromatophores.

The nominate subspecies *Caridina brachydactyla brachydactyla* De Man has been recorded from Indonesian Islands and Andaman Islands (Tiwari and Pillai<sup>2</sup>), from brackish as well as freshwaters. The subspecies *peninsularis* Kemp has been until now known only from the Malayan peninsula. The type material of Kemp<sup>1</sup> was from near Patani in Thailand and from a stream of clear water in the Botanic Gardens of Penang Island. Johnson<sup>3-5</sup> recorded it from Singapore, from some mainland streams as well as from tidal but non-saline waters.

It is of interest to note that near Guntur, the subspecies *peninsularis* has established itself in lentic bodies of freshwater not connected to an estuary. We have so far not come across this subspecies in the lower reaches of river Krishna. The shallow pond and pools which the subspecies inhabits are overgrown with *Typha*, *Vallisneria*, *Ottelia*, *Ceratophyllum* and other macrophytes; the shrimps occur among the vegetation.

We thank M/s. M. K. Durga Prasad and Y. Ranga Reddy, Research Fellows in this Department, for initially drawing our attention to the material. We are indebted to Dr. R. W. Ingle of British Museum (NH), London, for sending us relevant data of the syntypes. One of us (K. R.) thanks the authorities of CSIR, New Delhi, for the award of a Research Fellowship.

#### A NEW SANGUINICOLID CERCARIA FROM *AMNICOLA TRAVANCORICA* IN ANDHRA PRADESH

WHILE studying the infestation of freshwater snails with intra-molluscan stages, a cercaria belonging to a rare and little known group, viz., 'Sanguinicolid cercariae' was recorded from Balacheruvu in Kakinada, Andhra Pradesh. The cercaria was found emerging from one out of 37 snails belonging to the species *Amnicola travancorica* (Benson). This is the first report of a freshwater sanguinicolid cercaria from this country.

The methods of study were the same as suggested by Cable<sup>1</sup>. Cercariae for measurement were killed in hot water. All measurements are in mm. Figures are camera lucida drawings of heat killed, well-relaxed cercariae under coverslip, with the details added free hand.

The cercaria (Figs. 1 and 2) is small and the body is covered with small spines. The spines are larger at the anterior end. Tail is ventrally attached to the body, such that the body is almost at a right angle to the tail. Furcal rami are short, pointed and devoid of fin-folds. Both the tailstem and rami are covered with very small spines. Six to eight long bristles borne on conical elevations are present along the sides of the tailstem. There is no dorsal crest on the body. The tip of the body does not form an anterior penetrating organ as in the case of spirorchiid and schistosomatid cercariae, the oral sucker being absent. However, the spines at the anterior end are bigger and closely arranged. A pair of hollow piercing spines, characteristic of blood flukes are present at the tip of the body. Ventral sucker is absent. Ventral mouth leads into a long, club-shaped oesophagus that extends to about one-half of the length of the body. Caeca are absent. There are a large number of unicellular glands in the body; whether these glands represent the penetration glands could not be ascertained, as the ducts were not clear.

Excretory system is mesostomate (Fig. 2). Excretory bladder is small. There are three pairs of flamecells in the body and none in tail. A single caudal excretory tubule has been observed in the present study, as also by several other workers, in

closely related aporocotyloid cercariae (Sewell<sup>2</sup>, Mc Coy<sup>3</sup>, Holliman<sup>4</sup>, etc.), while Ejsmont<sup>5</sup> represented two caudal excretory tubules in the sanguinicolid cercaria studied by him.

FIG. 1. *Cercaria indicae* LXVI. n.s.p., entire cercaria lateral view.

FIG. 2. Body of the cercaria, lateral view, showing excretory and digestive systems.

**Measurements.**—Body length 0.092–0.105 and width 0.05. Tailstem 0.29–0.312 × 0.02–0.026, rami 0.84 × 0.013.

Cercariae emerge in moderate numbers in a day. Swimming is sporadic. Prolonged periods of rest alternate with an occasional attempt to swim. Cercaria rests with the tailstem bent on itself, and the rami crossing the stem, forming a characteristic looped structure.

Intramolluscan stages could not be studied as the snail host perished while the cercaria was being studied.

*Sanguinicolid cercariae can be characterised, as follows:* "Apharyngeate, brevifurcate, non-ocellate; dorsal fin-fold on body and furcal fin-folds may or may not be present, tail symmetrical or asymmetrical, anterior organ reduced or lacking; ventral sucker present or absent. Develop in

marine lamellibranchs or freshwater snails. Cercariae penetrate directly into fishes and develop into adults in the vascular system or rarely in the coelom".

The present species differs from all the described sanguinicolid cercariae except *C. hartmanae* Martin, 1952, *C. amphictis* Oglesby, 1961, and cercaria of *Sanguinicola davisi* Wales, 1958 in the absence of a dorsal fin-fold on body and furcal fin-folds. The present species differs from *C. hartmanae* in the absence of an anterior organ and ventral sucker, from *C. amphictis* in having a brevifurcate tail and from cercaria of *S. davisi* in being smaller and in the nature of the gut (intestine in the cercaria of *S. davisi* is four lobed) and in the attachment of the tail to the body (tail being posteriorly attached to the body in the cercaria of *S. davisi*).

The present species is named *Cercariae indicae* LXVI in continuation of the numbers used for Indian cercariae by Sewell<sup>2</sup>.

I am greatly indebted to Prof. K. Hanumantha Rao for his valuable suggestions. Thanks are due to the authorities of C.S.I.R. and U.G.C. for financial support.

#### CYPRIDOPSIS OCHRACEA SARS, 1924 (CRUSTACEA : OSTRACODA), A NEW RECORD FROM INDIA

WHILE studying the zooplankton fauna of Bihar, one of the authors (SAKN) came across Ostracoda, collected from a freshwater pond at Bhagalpur, Bihar. The specimens were identified as *Cypridopsis ochracea* Sars. These specimens have been deposited in the museum of the Zoological Survey of India, Calcutta, and the museum of the Post-Graduate Department of Zoology, Bhagalpur University.

A review of the literature reveals that the species is a rare one, and the only known record is by G. O. Sars from South Africa. This species is not recorded from the Indian sub-continent. The present note is intended to place on record the

actual occurrence of the species of *Cypridopsis ochracea* Sars from the Indian sub-continent. Since no description of this species is available in the Indian fauna for ready consultation, a brief description of the animal is given below.

**Structure of the animal.**—The animal has a total length of 0.78 mm, the height 0.50 mm and the width 0.30 mm. Shell small moderately tumid in dorsal view, cuneiform anterior end gradually compressed and acutely pointed, posterior end obtusely rounded, maximum width not nearly attaining half the length and occur little behind the middle (Figs. 1 and 2). In profile, oblong and trigonal form with the greatest height somewhat in front of the middle and not fully attaining three-fifth of the length, dorsal edge angularly bent just behind the ocular region and declining rather steeply with the margin slightly sinuate, anterior end obliquely rounded and posterior somewhat produced below. Surface unsculptured with the fine scanty hairs near the extremities. The structure of the specimen resembles that of the *Cypridopsis ochracea* as reported by Sars (1924).

FIGS. 1-9. Fig. 1. Dorsal view female. Fig. 2. Side view female. Fig. 3. Second antenna. Fig. 4. Second abdominal leg. Fig. 5. Maxilla. Fig. 6. First abdominal leg. Fig. 7. Furcal rami. Fig. 8. First antenna. Fig. 9. Maxilliped.

**Remarks.**—*Cypridopsis ochracea* Sars, is easily recognisable from any other forms recorded, by

the shape of the shell and its unusual light yellow colour, which is retained in specimens for a longer time even after preservation in alcohol.

Our sincere thanks to Professor J. S. Datta Munshi, Head, Zoology Department, Bhagalpur University, for his constant help and encouragement, to the Director, Zoological Survey of India, for identification. One of the authors (SAKN) extends his thanks to the C.S.I.R., New Delhi, for the award of a Research Fellowship.

### OCCURRENCE OF BIOVULAR FOLLICLES IN *HERPESITES JAVANICUS* AND *NYCTICEBUS COUCANG*

POLYOVULAR follicles and polynuclear oocytes have been reported in the ovaries of some mammals<sup>1-3</sup>. The present report embodies observations on the biovular follicles in *Herpestes javanicus* and *Nycticebus coucang*.

The ovaries of *Herpestes javanicus* and *Nycticebus coucang* were fixed in Bouin's fluid and 10% formalin. Paraffin sections were cut at 8 to 10  $\mu$  thick, and stained with Ehrlich's hematoxylin-eosin and periodic acid-Schiff procedure.

In *Herpestes javanicus* biovular follicles at the multilaminar follicular stage of development are found situated towards the periphery of the ovary. The two oocytes of the multilaminar biovular follicle (Fig. 1) are approximately equal in size, and are separated by the cells of membrana granulosa. Each oocyte of the biovular follicle has a single eccentric nucleus and is surrounded by a distinct PAS-positive zona pellucida. The cells of the membrana granulosa are round in shape, each having a darkly stained centrally placed nucleus. The ovary containing biovular follicles has a corpus luteum of early pregnancy. A few atretic follicles and a large number of primary oocytes are also present in the same ovary.

In *Nycticebus coucang* biovular follicles are situated towards the periphery of the ovary. The

two oocytes of the biovular follicle (Fig. 2) lie in direct contact with each other and are of equal size. Each oocyte of the biovular follicle has a centrally placed nucleus.

FIGS. 1-2. Fig. 1. Photomicrograph of a biovular follicle of *Herpestes javanicus*. Magnification on  $\times 220$ . Fig. 2. Photomicrograph of a biovular follicle of *Nycticebus coucang*. Magnification,  $\times 250$ .

In both these animals, biovular follicles are not seen beyond multilaminar follicular stage. It is likely that these follicles may undergo atresia. Whereas in *Herpestes javanicus* the two oocytes of the biovular follicle are separated by the cells of membrana granulosa, in *Nycticebus coucang* the two oocytes of the biovular follicle lie in direct contact with each other.

# ON THE NUCLEAR POLYHEDROSIS OF *PLUSIA CHALCYTES* ESP. (LEPIDOPTERA: NOCTUIDAE)

NUCLEAR polyhedrosis has been reported in *Plusia gamma* L. by Lepine *et al.* (1953) and *P. chalcytes* Esp. by Laudeho and Amargier (1963). The present communication deals with the occurrence of nuclear polyhedrosis in larvae of *Plusia chalcytes* Esp. (= *P. eriosoma* Dbl.) feeding on groundnut (*Arachis hypogaea* L.) and *Flaveria australasica*. This appears to be the first record of nuclear polyhedrosis in *P. chalcytes* from India.

Infected caterpillars exhibited typical symptoms of nuclear polyhedrosis with rupturing of integument. On inoculation, the polyhedral suspension was found to be highly infective to third and fourth instar caterpillars. The incubation period of the virus in fourth instar caterpillars ranged from five to seven days. The inclusion bodies were somewhat triangular in shape (Fig. 1) and ranged from  $0.64$  to  $1.35 \mu$  in diameter with a mean of  $0.98 \mu \pm 0.01$ .

FIG. 1. Electron micrograph of polyhedra isolated from *P. chalcytes*. Line =  $0.674 \mu$ .

Paraffin sections of infected caterpillars revealed the presence of polyhedra in the nuclei of fat body, hypodermis, tracheal matrix, muscles, nerve sheath, hind gut, malpighian tubules and testicular epithelium. The nuclei of the midgut epithelial cells were found to be hypertrophied with some dark stained particles. This may indicate replication of the virus in the nuclei of the epithelial cells of the midgut as reported by Laudeho and Amargier (1963) in *P. chalcytes* but it requires confirmation electron microscopically.

The authors are grateful to Dr. Jean R. Adams, Research Entomologist, Insect Pathology Laboratory, Beltsville, Maryland, for making the electron micrograph and confirming the identity of the virus.

### CROSS INFECTIVITY OF NUCLEAR POLYHEDROSIS OF *AMSACTA ALBISTRIGA* WALK. TO OTHER SPECIES OF LEPIDOPTERA

RESULTS of recent work on possible cross infection of polyhedrosis between closely related and unrelated Lepidoptera have been reviewed by Aizawa<sup>1</sup>, Huger<sup>2</sup> and Smith<sup>3</sup>, and it appears that insect viruses are far from being species specific as was once thought. Knowledge of the cross infectivity of insect viruses is of theoretical and practical importance, especially in the area of virus epizootiology and microbial control. This paper presents the results of inoculation tests with NPV of *Amsacta albistriga* Walk. (Arctiidae) on thirteen species of Lepidoptera.

Apparently virus free larvae of 1 to 5 days old were fed with NPV of *Amsacta albistriga* as inclusion bodies by contaminating the foliage of respective host plants with 10<sup>6</sup> polyhedra per ml. The insects tested were *Pericallia ricini* Fab. (Arctiidae), *Euproctis fraterna* Moore., *Notolophus posticus* Walk. and *Porthesia scintillans* Walk. (Lymantridae), *Earias vitella* Fab., *Spodoptera litura* Fab., *Heliothis armigera* Hub., *Orthago exivaneae* M. and *Cosmophila erosa* F. (Noctuidae), *Hyblaea parea* Cramer (Hyblaeidae), *Eupterote mellifera* Walk. (Eupterotidae), *Papilio demoleus* L. (Papilionidae) and *Sylepta derogata* Fab. (Pyralidae). The inclusion bodies were from semipurified stock of 5 to 7 months old. However, 100% infectivity was retained even after one year on *Amsacta albistriga*. The cause of death of test insects was diagnosed microscopically with squashed preparation. Cadavers having inclusion bodies in tissues were scored as virus-infected and those lacking inclusion bodies as negative.

It was evident from the results that nuclear polyhedrosis virus of *Amsacta albistriga* was not cross infective to the 13 species of Lepidoptera tested. Most of the test species died of bacterial

infection and of other unknown causes. The rest pupated normally without any pathological changes. No natural incidence of viruses were reported for the species tested except in *Spodoptera litura* (Nuclear polyhedrosis<sup>4</sup>), and *Pericallia ricini* (Nuclear polyhedrosis and granuloses<sup>5</sup>). Since these two species were not cross infective to NPV of *Amsacta albistriga* the possibility of induction of latent virus infection was ruled out. The negative results agree with older view of Steinhaus<sup>6</sup> that a high degree of host specificity is a characteristic of insect viruses.

### EFFECT OF CROP AGE ON FIBRE QUALITY (TENACITY) IN JUTE (*CORCHORUS* SP.)

ALTHOUGH the jute crop is generally harvested soon after formation of pods, earlier harvesting is often found necessary, particularly for fitting it in a suitable crop rotation. While there is evidence of reduction in fibre yield when early harvesting is resorted to, not much information is available with regard to its effects on fibre quality. The present study was undertaken at the Block Seed Farm, Singur, Hooghly, in 1972, with a number of *C. olitorius* types and was repeated at the Seed Multiplication Farm, Chinsurah, in the same district, in 1973, to ascertain how far the tenacity of fibre, a very important quality character, is affected by advancing the date of harvest. The layout and different cultural operations were similar in both the years, but the retting conditions were a little different, stagnant water being used in the former and slow moving water in the latter. In the second year, a similar separate experiment was undertaken with types of *C. capsularis*.

In 1972, 23 types of *C. olitorius* were sown in two replications, each unit plot consisting of a single row of 1 metre length having 15 plants. Three plants were harvested at random from each

row at crop ages of 90, 100, 110 and 120 days. The tenacity of fibre of each type was determined with the help of a 'bundle tester', as is done at the Jute Technological Research Laboratories, Calcutta. In 1973, the study was repeated with 21 of these types along with 5 others, and one extra harvest at 130 days' crop age was investigated. In addition, 23 *capsularis* types were tested separately.

Typical values of fibre tenacity are given in Tables I and II to indicate the nature of the results.

## Tenacity Grades

1. Very good — above 29.0
2. Good — between 25.1 and 29.0
3. Fairly good — between 21.1 and 25.0
4. Average — between 17.0 and 21.0
5. Bad — below 17.0

It is seen in Table I that, despite somewhat erratic performance of certain types, the tenacity of fibre, on the whole, decreased with delay in harvesting. While the types barring only a few were good or

very good in tenacity at the crop age of 90 days, there was a fall in each case as the date of harvest was deferred, and, at the last harvest (at 120 days and 130 days in 1972 and 1973 respectively), almost all the types, irrespective of their earlier performance, were found to be bad (tenacity being below 19). Even the types, which recorded very high tenacity values (above 31) at 90 days, registered in many cases fairly big fall with a delay in harvesting. The performance of *capsularis* types (Table II) was more or less similar to that of *olitorius* in so far as the decrease in tenacity of fibre with delay in harvesting was concerned. However, unlike the latter, the former showed an increase in tenacity at 100 days' age, after which the decrease actually started. This indicated that, while in *olitorius*, the first date, i.e., 90 days' crop age was found to be the best of all the dates considered, in *capsularis*, the second date, i.e., 100 days' crop age, was the best. This decrease in tenacity of fibre in both the species as the harvesting was delayed was probably due to the adverse effects of increasing age. In the case of *olitorius*, the correct period appears to be 90 days or even less and in the other species, 100 days was found to be the best.

Of the *olitorius* types studied, Tanganyika-I, which was studied in the second year only, recorded almost the same value till the third harvest, there being a slight fall in the fourth. Even at this stage, there was a little deterioration in tenacity. It was only at the age of 130 days that an appreciable decrease was observed and the tenacity was found to be fairly good. JRO 878, which was studied in both the years, showed considerable differences between the tenacity values of the two years at a particular crop age. However, the data, particularly of the second year, indicated that the variety was quite stable till the age of 110 days. In the case of *capsularis*, only one of the types, JRC 321, showed some stability till the last harvest.

The tenacity values, recorded in the second year at the crop age of 130 days, appeared on the whole, more or less similar to that of the first year at 120 days' age (Table I). The reasons for this difference can perhaps be traced to the difference in retting conditions. It may be that the quality of fibre of the later charges in the first year was adversely affected because the same water was used over and over again.

A detailed study is proposed to be taken up shortly to ascertain the exact reasons for deterioration in fibre tenacity of jute with an increase in crop age.

Thanks are due to the Director, Jute Technological Research Laboratories, Calcutta, and the Director

of Agriculture, West Bengal, for providing the necessary facilities.

### A REPORT ON TRANSITION IN THE STOMATAL SIZE WITH AGING OF LEAVES IN *CLEOME VISCOSA* LINN.

POLYMORPHISM in the stomata has been recorded in a few plants<sup>1-4</sup>. During survey of stomata in arid zone plants, it was discovered that there is a distinct variation in stomatal size of *Cleome viscosa*. This is a very common plant growing wild in the rainy season. Plants were demarcated from different habitats under different conditions in the Jodhpur University campus. Three types of leaves were graded according to their maturity or aging (young, adult and old). Epidermal peelings were made from the abaxial surface of the leaf and stomatal measurements were made with the help of precalibrated microscope. The measurements are tabulated in Table I.

number of epidermal cells with the maturity of the leaves. Epidermal cells form a beak like structure on both the edges of stomata. Stomata with a single functioning guard cells were also

| Adult       | 593±54                      | 30                         | 21       | 27       | 21       | 24       | 18       | 21       | 18       | 2070±193                       | 22.3              |
| Old         | 340±46                      | 33                         | 24       | 30       | 21       | 27       | 21       | 24       | 18       | 1293±154                       | 20.8              |

*l*=Length of stomata; and *b*=Breadth of stomata.

It is evident from Table I that the number of stomata and epidermal cells per unit area decrease with the maturity or aging of leaves. Old leaves have fewer stomata and epidermal cells as compared to young ones. It is a well known fact that stomata continue to develop through a considerable part of the epidermal extension of the leaf by cell enlargement<sup>5</sup>, and new stomata would hardly arise when a leaf has attained full maturity. As per stomatal measurements, the stomata appear to fall in more than one group. It may appear that hardly new stomata arise in a mature leaf. Stomatal measurements at random show four distinct groups. The smallest stomata were seen only in the young leaves and the largest in the old ones only. Stomata of four sizes were seen common in all ages of leaves. The number of stomata of size  $27 \times 21 \mu$  and  $24 \times 18 \mu$  were common to all ages of leaves (Fig. 1). This indicates that there is an increase in the size of stomata and decrease in the

observed. Thus from the present study a correlation can be made between: (1) the number of stomata and number of epidermal cells; (2) number of stomata and maturity of leaf; (3) size of the stomata and maturity of leaf in this species.

The authors are thankful to Prof. H. C. Arya, Head, Department of Botany, for providing necessary facilities.

ON THE IDENTITY OF *HABENARIA*  
*GRANDIFLORIFORMIS* BLATT. McC.

*Habenaria grandifloriformis* Blatt. McC. and *H. grandiflora* Lindl. are considered to be duplicates taxonomically on the basis of similarities in the floral structure (Santapau and Kapadia, 1966). It was the hope of the author to evaluate the position of these species on their growth habits, morphology and anatomy of the vegetative organs.

The plants possess a very short stem that emerges out from a globose-ellipsoid special tuberous mother root, bearing usually a single leaf lying flat on the ground (Fig. 1). The stem bears a few short but stout roots and one among them has a swollen tip and forms the special tuberous root. In all the special tuberous roots studied, a single bud or two buds are initiated endogenously at the basal part of the tuber enclosed within a cavity. At a later stage these bud initials enlarge and get exposed as small protuberances.

Fig. 1. *Habenaria grandifloriformis* Blatt. McC., entire plant; tm, tuberous mother root; tr, tuberous root.

Towards the end of the season the stem along with the wrinkled spongy special tuberous root remains underground, alive till the next monsoon when it develops a new plant. Then this special

tuberous root turns out to be the special tuberous mother root of that plant. This growth habit is repeated in the following seasons.

The specimens collected for the present investigation befit the taxonomical descriptions of both *H. grandifloriformis* and *H. grandiflora*, and revealed identical features of the corresponding vegetative organs. The morphology and anatomy of the vegetative organs, viz., root, special tuberous roots, stem and leaf, as brought out by this study, invariably show striking similarities between the two plants and a distinction of the two species becomes impossible.

NEW RECORD OF LONG GRAIN IN RICE

VARIATION in grain length in rice has been reported by number of workers. The longest (14.23 mm) grain was obtained in Ac. 27 an introduction from China<sup>1</sup>. The variety SML 128/4 from Surinam had been reported to have a grain length of 14.40 mm<sup>2</sup>.

During a study carried out at the Central Rice Research Institute, Cuttack, on grain size, two long grained varieties Ac. 27 and Roti (grain length—13.15) from Madhya Pradesh were crossed in Kharif—1972.

The average grain length of Ac. 27 is 14.19 mm (range—13.98 to 14.50 mm). The grain length of Roti ranged from 12.68 to 13.58 mm with a mean of 13.15 mm. In the  $F_1$  plants the grains were intermediate in length (13.25 mm). In the  $F_2$  generation grain length ranged from 9.57 to 16.17 mm. Out of 530 plants studied 8 were in the transgressive class for longer grain. These 8 plants were carried over as plant progenies and in the  $F_4$  generation, one culture possessing average grain length 16.09 mm, was isolated. This was further studied in  $F_5$  and found to breed true. The grain development is normal. This is now being maintained. The detailed information about this culture as well as the parents is furnished in Table I.

The variation in grain type in  $F_2$  is shown in Fig. 1 along with that of  $F_1$  and parents.

Grain length exceeding 14.4 mm had not been reported earlier and the present observation is first of its kind. The test weight (1000 grain) was, however, less than Ac. 27 and this may probably be due to reduced breadth and thickness in addition

KARYOTYPE STUDY IN  
DIPCADI CONCANENSE DALZ.

THE genus *Dipcadi* is chiefly an African genus and in India eight species are reported to occur. All the Indian species flower in June and July and disperse seeds by August.

The cytology of the Indian species is not known in sufficient detail except for the report of the karyotypes in three species by Mahabale and Chennaveeraiah<sup>2</sup>. In the present paper the chromo-

somes number and karyotype of *D. concanense* is given and this is the first record. The material for the present study was collected by Prof. M. S. Chennaveeraiah from Malwan (Maharashtra). This species is apparently endemic and is distinguished from the rest by its large white flowers. The root tips were excised, pretreated with 0.002 molar 8-hydroxyquinoline for 4 hours at 10–15° C and squashed in aceto-orcein. For the description of karyotype the method followed by Levan *et al.*<sup>1</sup> has been adopted. For determining the type of chromosome the centromeric index  $r = (l/s)$ . Where  $r$  as the arm ratio,  $l$  as the length of the long arm and  $s$  as the length of the short arm is taken into account.

Twelve chromosomes were counted from the root tip cells. Somatic metaphase chromosomes and the idiogram are shown in Figs. 1–2. There are

FIGS. 1–2. Fig. 1. Photomicrograph of somatic metaphase (2n = 12) in *Dipcadi concanense*, × 1800. Fig. 2. Idiogram of the above.

3 pairs of long and 3 pairs of short chromosomes. Two pairs of long chromosomes have satellites on their short arms. Excepting one pair in which the centromere is terminal, in all the other pairs of chromosomes the centromere is submedian. The details of the karyotype are given in Table I.

TABLE I

Karyotype analysis in *Dipcadi concanense* Dalz.

| Chromosomes | Length in microns |               | Arm ratio | Centromere |
|-------------|-------------------|---------------|-----------|------------|
|             | Long arm          | Short arm     |           |            |
| I           | 5.50              | 2.20<br>+0.55 | 2.50      | sm SAT     |
| II          | 4.68              | 2.48<br>+0.99 | 1.82      | sm SAT     |
| III         | 6.60              | 0.83          | 7.95      | t          |
| IV          | 2.20              | 0.83          | 2.65      | sm         |
| V           | 1.79              | 0.83          | 2.15      | sm         |
| VI          | 1.51              | 0.83          | 1.81      | sm         |

It is significant to note that Mahabale and Chennaveeraiah<sup>2</sup> have also observed two pairs of satellited chromosomes in all the three species they have studied, and this is indicative of evolutionary relationships in the genus. Further, in this species although the chromosome number is the same as that of *D. saxorum*, the karyomorphology is entirely different from it. Both the species have very restricted occurrence.

#### A NEW STOMATAL TYPE

THIS note reports a type of stoma which doesn't find a place, either in Metcalfe's (1950)<sup>2</sup> classification, or in the more recent one of Fryns Classaens and Van Cotthem (1973)<sup>1</sup> and suggests a name for it, for inclusion in the latter classification.

The author, in his studies on epiphytic orchids<sup>3,4</sup>, encountered stomata with three subsidiary cells, all of which are more or less of equal dimensions. He has observed them, also in *Aerides crispum* Lindl. *Porpax jerdoniana* (Wt.) Rolfe. The nearest type to this type of stoma, in Metcalfe's classification, is the 'anisocytic', which becomes 'anisomesogenous' or 'anisomesoperigenous' in Fryns Classaens and Van Cotthem's classification, in all three of which there are three subsidiary cells, out of which one is distinctly smaller than the other two. The author suggests the term 'isomesoperigenous', as a new type, for a three subsidiary-celled stoma, where all the three cells are of equal dimensions, as exemplified by the aforementioned plants, to be included

in the latter classification, under the mesoperigenous types.

FIG. 1. An isomesoperigenous stoma from the leaf epidermis of *Aerides crispum* Lindl.

However, the recent classification too does not solve the basic problem, viz., the identity of the subsidiary cell, in epidermes where ordinary epidermal cells and those in the vicinity of the stomata, look alike morphologically, at maturity. It is possible to presume that they are truly subsidiary (in the ontogenetic sense), if there were but only one ontogenetic method of a particular type of stoma being developed, which need not necessarily be the case always.

#### FUNGISTATIC PROPERTIES OF SOME SEEDLING EXTRACTS

THE tender seedling stage of a higher plant appears most vulnerable to infection by pathogens. But a large number of plants are able to escape infection, thereby indicating the presence of some fungistatic substance(s) in them. It was this aspect which prompted us to undertake the screening of seedlings for their fungistatic activity.

Seeds of various species (Table I) were allowed to germinate on moist filter paper in sterilized petriplates for two to three weeks and the seedlings were tested for fungistatic properties. Entire seedlings were crushed thoroughly to extract the juice, which was tested immediately against *Cephalosporium sacchari* Butl. and *Fusarium nivale* (Fries)

Cesati, by slide germination technique<sup>1</sup>. Percentage of spore inhibition was noted after 24 hours and the fungistatic activity was measured in terms of this percentage.

TABLE I  
Inhibition of spore germination by seedling extracts

| S. No. | Genus and species  | % inhibition of spore germination |                        |

| 30     | Controi  | 99.98                             | 100.00                 |

Out of 29 taxa screened, the extract of four showed strong fungistatic activity against both test fungi (Table I). The extracts of six other species were partially active, inhibiting spore germination of either of the two test fungi. Surprisingly the extracts of *Brassica juncea* L. and *Brassica pekinensis* Lour. (5 and 7 in Table) stimulated the germination of fungal spores.

Table also shows that fungistatic property is neither a family character nor a generic one. It varies from family to family, from genus to genus

from species to species. A plant species which partially inhibited one fungus was found to be completely inhibitory to other one.

Further study is needed to isolate the fungistatic substance(s) from these seedling extracts. The authors are thankful to Prof. K. S. Bhargava, for providing laboratory facilities and encouragement to Dr. R. R. Upadhyay, for various suggestions and to the S.C.S.I.R., (U.P.), for financial assistance.

### THE GENUS *PSEUDOBOTRYTIS* KRZEMIENIEWSKA AND BADURA

THE genus *Pseudobotrytis* was created by Krzemieniewska and Badura (1954)<sup>1</sup> with the type species *P. fusca*. Timonin (1940)<sup>4</sup> and Morris (1955)<sup>2</sup> described the same fungus as *Spicularia terrestris* Timonin and *Umbellula terrestris* (Timonin) Morris respectively. Subramanian (1956)<sup>3</sup> found that *P. fusca* K & B. and *U. terrestris* (Timonin) Morris were identical and congeneric and, therefore, he proposed a new combination *Pseudobotrytis terrestris* (Timonin) Subram. In 1961 Tironin<sup>5</sup> isolated from soil in Honduras a new species of this genus, *P. bisbyi* Timonin.

Recently the authors collected dead twigs bearing black fungal growth from Mt. Abu. The present fungus closely resembles *P. bisbyi* Timonin except that the conidiophores are short. *P. bisbyi* has not so far been recorded from other parts of the world and hence this is the first record of this fungus from India.

#### *Pseudobotrytis bisbyi* Timonin

Fungus forming effuse, blackish growth on the dead twigs. Repent vegetative hyphae brown, branched, septate, upto  $5.5\mu$  broad, producing 1-2 rhizoid like hyphae at the point of origin of conidiophores. Conidiophores arising laterally from cells of the repent hyphae, length upto  $120\mu$ , unbranched, simple, erect, straight, septate, distance between septa upto  $27\mu$ , dark-brown with the apical cell  $20-24.5 \times 4.0\mu$  being hyaline, slightly tapering towards the tip, breadth at the base  $5.4-6.7\mu$ , breadth at the middle  $4.7-5.4\mu$ ; tip globose,  $6.7 \times 5.4\mu$ , denticulate and bears a verticil of about 12 simple, hyaline, sterigma-like branches of nearly equal length,  $21.6-27.5 \times 2.5-4.0\mu$ , thick at the base, and gradually tapering towards the apex, finally each of which in turn terminates in

a nearly globose to elliptical tip. diameter of the tip  $6-6.7 \mu$ , bearing many conidia produced singly on minute, short pegs. Conidia ovate to oblong, 1-celled, pale-brown to fuliginous, smooth-walled, with a minute basal scar indicating the point of attachment,  $5-6.7 \times 3-4.7 \mu$  (Fig. 1).

# AN INTERESTING ASCOMYCETE FROM COORG (KARNATAKA)

DURING a tour in the Coorg Forests an interesting ascomycetous fungus was collected growing on the twigs of *Lobelia trigona* Roxb. The infected areas were in the nature of stroma forming a thin, black, carbonaceous outer layer on the host. Critical examination of the material further revealed its identity as a species of *Pleuroceras* Riess. (Diaporthaceae)<sup>1</sup>, hitherto an unrecorded genus in India. For its identity, the fungus was studied in detail and found to be distinct, differing significantly from *Pleuroceras cryptoderis* (Lev.) v. Hohn.<sup>2</sup>, the type species, as well as *P. populi* Thompson<sup>2</sup> in respect of gross-morphological characters and dimensions of fruiting structures, besides being collected on a new host. Hence, the same has been described here as a new species, viz.,

*Pleuroceras lobelii* sp. nov. (Fig. 1)

Stromata nigra, levia, coriaceo-carbonaceis tenui; perithecia rostellata, tenuiter-tunicata, membranaceo, defixus oblique in plantis textus, ostiolata, usque ad 1-2 per stroma, magnit:  $340-510 \times 255-340 \mu$ ; collo brevia vel piriformibus,  $136-170 \times 80 \mu$ , diagonalia et lateralia oriunda; periphyses numerosae, filiformae hyalinae; paraphysibus nullae; asci octospori, unitunicati, apophysatae, cylindracei vel clavati, emergentes in fasciculo, magnit:  $95-114 \times 9.5-11.4 \mu$ ; ascospores bicellulares, hyalinae, tenuiter-tunicati, forma fusus, constrictae ad septa,  $22.8-30.4 \times 2-3.8 \mu$ .

FIG. 1. *Pleuroceras lobelii*. A, Habit; B, V. S. through a stroma; C, Asci; D, Ascospores.

Matrix: In culmis emortuis *Lobelia trigona* Roxb. (F. Lobeliaceae). Leg. D. V. Narendra (November 11, 1971), ad Mercara (Coorg, Karnataka), No. AMH 2188 (Holotypus).

Grateful thanks are offered to Prof. M. N. Kamat for his keen interest, to Dr. Emil Muller, Institute of Special Botany, Zurich (Switzerland), for kindly

confirming the identity of the fungus and to the Director, M.A.C.S., Poona, for laboratory facilities.

### RESISTANCE OF TOMATO CULTIVARS TO THE ROOT-KNOT NEMATODE, *MELOIDOGYNE INCOGNITA*

(KOFOID AND WHITE, 1919) CHITWOOD, 1949

ROOT-KNOT nematodes constitute one of the important pests of vegetables in India. Solanaceous crops including tomato suffer from heavy damage when grown in soil infested with *Meloidogyne incognita* and *M. javanica*.

In any nematode control programme, development of nematode resistant varieties constitute an important objective. In addition to chemical and crop rotation methods. Some cultivars and selections have been reported to show resistance to root-knot nematodes by various workers<sup>1-6</sup>.

Five tomato varieties were assessed for their relative resistance to the root-knot nematode, *M. incognita*, at the Experimental Station, Hessarghatta, Indian Institute of Horticultural Research, Bangalore. Cultures of *M. incognita*, maintained on tomato variety, Pusa Ruby, were used as the inoculum source. Seedlings of different varieties raised in nematode free soil (soil treated with D-D at the rate of 60 gallons/acre and stored in wooden boxes for about 6 months) were transplanted in 6" clay pots. At transplantation 100 gm of infested soil (about 5,800 larvae in 100 gm of soil) was added around the root system in each pot. Six replicates were kept for each variety. After 10 weeks the plants were carefully uprooted by breaking the pot and washing the roots under running tap water. The root-knot index was obtained on a scale of 1-5 with the plant showing an index between 1 and 2 rated as resistant (Table I and Fig. 1).

The varieties Pelican, Hawaii-7746, Hawaii-7747 were found resistant to *M. incognita*, with a root-knot index of 1.5, 1.17 and 1.17 respectively, whereas *Lycopersicon pimpinellifolium* and the variety Pusa Ruby with a root-knot index of 4.00 and 5.00 were susceptible.

Dropkin *et al.*<sup>1</sup> have shown that *L. pimpinellifolium* was susceptible to *M. hapla* and *M. incognita acrita*. Khan *et al.* have reported in their

TABLE I

Root-knot index of tomato varieties that show differences in resistance after transplanting in soil infested with *Meloidogyne incognita*

| Variety                              | Root-knot index <sup>a</sup> |
|--------------------------------------|------------------------------|
| Pelican                              | 1.50                         |
| Hawaii-7746                          | 1.17                         |
| Hawaii-7747                          | 1.17                         |
| Pusa Ruby                            | 5.00                         |
| <i>Lycopersicon pimpinellifolium</i> | 4.00                         |

<sup>a</sup> : 1=no galling on roots; 2=1-25% galled; 3=26-50% galled; 4=51-75% galled and 5=76-100% of roots galled.

FIG. 1. Roots of different tomato varieties showing different degrees of infestation : Pelican, Hawaii-7746, 7747—Resistant. *L. pimpinellifolium* and Pusa Ruby—susceptible.

studies that *L. pimpinellifolium* to be resistant to *M. incognita* while here it has been recorded as susceptible. It is quite possible that there may be a variation in the species. *L. pimpinellifolium* or there may be existence of different strains in *M. incognita*. Sikora *et al.*<sup>5</sup> reported a similar observation with respect to screening of root-knot nematode resistant tomato cultivars against *M. javanica*. They observed that two resistant varieties VFN-8 and VFN-368 were found heavily galled to a Pant Nagar population. This shows that the known resistant varieties should be carefully screened against the local populations of root-knot nematodes before they are recommended for a particular area for cultivation or before their inclusion in a breeding programme.

The authors are grateful to Dr. G. S. Randhawa, Director, for his encouragement to carry out this work. Thanks are also due to Dr. V. G. Prasad

for going through the manuscript and to Dr. M. V. B. Rao for the supply of Hawaiian lines.

#### EMBRYOLOGICAL STUDIES IN *MEINECKIA* *PARVIFOLIA* (WIGHT) WEBSTER

THE genus *Meineckia* Baill. of the Euphorbiaceae, belongs to the tribe Phyllanthae of the subfamily Phyllanthoideae. Webster<sup>1</sup> recognised 19 species in the genus and drew attention to the extraordinary confusion in the taxonomic history of the genus in that the various species were earlier included in six different genera: *Cluytiandra*, *Flueggea*, *Neopeltandra*, *Peltandra*, *Phyllanthus* and *Securinega*. Of the 19 species recognised, four species are represented in India and Ceylon and *Meineckia parvifolia* is one of them. This species of somewhat infrequent occurrence in South India was treated by Gamble<sup>2</sup> as *Neopeltandra suberosa* which in its turn was synonymous with *Phyllanthus suberosus* Muell. Arg. Gamble erected the genus *Neopeltandra* to be distinct from *Phyllanthus* based on the number of stamens which is 5 in *Neopeltandra* and 3 in *Phyllanthus*. However, Webster took into consideration a combination of vegetative, floral, capsular and seed characters (especially the occurrence of a pistillode in the male flowers and the structure of the seed) merged it with the genus *Meineckia*. So far, there is no information on the embryology for any species of this interesting genus.

In *Meineckia parvifolia*, the male archesporium is formed by a single row of hypodermal cells. The wall of the quadrisporangiate anther consists of an epidermis, fibrous endothecium, two middle layers and a secretory type of tapetum with a single layer of binucleate cells. The divisions of the pollen mother cells are simultaneous and cytokinesis takes place by furrowing and tetrahedral type of

pollen tetrads are formed. The pollen grains are shed at the 2-celled stage (Fig. 1) and according to Punt<sup>3</sup> they resemble those in various unspecialized genera of the Phyllanthae. Kohler<sup>4</sup> made no mention about the pollen grains in this genus.

The ovary is superior, tricarpeal syncarpous and trilocular with a pair of collateral, bitegmic anatropous, crassinucellate ovules in each loculus on axile placentation. An obturator is developed from the placental region<sup>5</sup> (Figs. 2, 3). The female archesporium is single celled (Fig. 4) and cuts off a parietal cell and the resultant megaspore mother cell becomes deep seated (Fig. 5). The embryo sac development is of the Polygonum type (Figs. 6, 7). These features are similar to those of investigated species of the genus *Phyllanthus*<sup>6-8</sup>.

The endosperm is of the Nuclear type. The first division of the zygote is transverse giving rise to a 2-celled proembryo (Fig. 8). The apical cell *ca* divides vertically and the basal cell *cb* transversely and thus the 4-celled proembryo at the end of the II cell generation has its four cells arranged in three tiers (Fig. 9) as in *Phyllanthus grandifolius*<sup>9</sup> and unlike in other species of *Phyllanthus* studied<sup>6-8</sup>. A quadrant *q* is formed in the tier *ca* (Fig. 10). Transverse divisions in each cell of the quadrant differentiate an octant comprising two tiers *l* and *l'* of four cells each (Figs. 11, 12). The middle cell *m* undergoes a vertical division and behaves as the hypophyseal initial (Figs. 10-15). The cell *ci* undergoes a transverse division and forms a bicelled suspensor (Figs. 12-15). The derivatives of the

FIGS. 1-15. Fig. 1. 2-celled pollen grain. Figs. 2, 3. Long sections of ovules at the mmc and linear tetrad stage, respectively. Figs. 4, 5, 6. Long sections of part of ovules showing stages in the megasporogenesis. Fig. 7. Mature embryo sac. Figs. 8-15. Stages in the embryo development.

tier 1 contribute to the stem tip and cotyledons, those of 1' to hypocotyl and radicle, and those of *m* to the root tip and root cap. Hence the embryogeny falls under the Period I, Series A, Megarchetype IV according to Souèges (see Crété<sup>10</sup>) or keys out to the Euphorbia variation of the Onagrad type according to Johansen<sup>11</sup>.

There is no significant embryological data for species of the genera, *Chytandra*, *Flueggea*, *Neopeltandra*, *Peltandra*, and *Securinega* with which *Meineckia* was formerly associated excepting 5 species of *Phyllanthus* (this genus has 480 species). Comparative embryological approach, hence tends to be inconclusive. Webster, however, singled out the seed characters as the best, diagnostic feature for the genus. Further embryological work on species of *Meineckia* is in progress to find the implications of embryology, correlated with data on other grounds, in evaluating the status of the genus.

I wish to express my sincere thanks and gratitude to Prof. J. Venkateswarlu for guidance and encouragement. I am grateful to Prof. Grady L. Webster, of the University of California, USA, for providing me with valuable literature and useful correspondence on this topic. My thanks are due to Mr. D. Sarveswara Rao for help in preparing this paper.

#### OCCURRENCE OF AECIAL AND PYCNIAL STAGES OF *PUCCINIA HELIANTHI* SCHW. IN INDIA

SUNFLOWER rust, caused by *Puccinia helianthi* Schw., has been reported from Bombay on *Helianthus annuus*<sup>1</sup>. But in Coimbatore, though this rust has been observed very early in the twenties itself no published report of its occurrence appears to have been made<sup>2</sup>. Siddiqui<sup>3</sup> noted only the uredial

and telial stages of this rust on the variety "Sunrise" at Coimbatore.

Though this rust has been reported to be autoecious as early as 1934 by Arthur<sup>4</sup>, the aecial and pycnial stages do not appear to be of common occurrence. Perisic<sup>5</sup> reported aecial and pycnial stages from Yugoslavia. No record of the occurrence in India of these two stages of the rust is available. During the last week of August 1974, the aecial and pycnial stages of this rust were observed in the campus of the Tamil Nadu Agricultural University on the leaves of 85 day's old plants of the sunflower variety EC 68413 heavily infected by *P. helianthi*, along with the uredial stage.

The pycnia are amphigenous, aecia hypophyllous cupulate and aeciospores globoid, wall colourless and minutely verrucose (Fig. 1). This appears to

FIG. 1. Transverse section of Sunflower leaf showing aecia and pycnia.

be the first record of the aecial and pycnial stages of the rust in India. Studies on the life-cycle and host range of this rust are in progress.

Our grateful thanks are due to Dr. T. K. Kandasamy, Head of the Department of Plant Pathology, for providing all facilities and encouragement.

## SHORT SCIENTIFIC NOTES

### A New Indicator for Direct EDTA Titration of Zinc Ions

The present note describes the use of diphenyl carbazide as indicator for the direct EDTA titration of zinc ions. The stock solutions of zinc sulphate, EDTA and indicator were 0.1 M, 0.01 M and 1.0% respectively. Solutions of interfering ions were 0.2 M.

Diphenyl carbazide gives a pink colour with zinc ions. There is a sharp colour change on titration with EDTA from pink to pale yellow at the end point. When an aliquot of  $Zn^{2+}$  solution is titrated with EDTA, zinc can be estimated accurately in the pH range 2.0–3.0 with the help of the indicator investigated. Titrations, carried out with different concentrations of the indicator, showed that an addition of 2 drops of 1.0% solution of the indicator gave satisfactory results for 5–10 ml of 0.01 M zinc sulphate solution. The titration could be satisfactorily carried out in the temperature range 10–60° C. At 1.5 mg concentration of zinc, 50 times excess of  $Na^+$ ,  $K^+$ ,  $NH_4^+$ ,  $Cr^{3+}$ ,  $NO_3^-$ ,  $SO_4^{2-}$ , 5 times excess of  $Ni^{2+}$ ,  $Co^{2+}$ ,  $Mg^{2+}$ ,  $Mn^{2+}$  and 2 times excess of  $Ca^{2+}$ ,  $Sr^{2+}$ ,  $Ba^{2+}$ ,  $Cl^-$  and  $Cu^{2+}$  could be tolerated. Similar observations for other ions and indicators have been reported<sup>1-3</sup>.

Take 5.0 ml aliquot of 0.01 M zinc sulphate solution, adjust pH 2.0–3.0 using 1–2 ml solution of acetate-HCl buffer of pH 2.0, add 2 drops of 1.0% solution of the indicator and titrate against 0.01 M solution of EDTA to pale yellow colour.

5.0 ml aliquots of 0.01 M zinc sulphate were analysed according to the suggested procedure. The standard deviation was 1.0%.

### A Gravimetric Method for Estimating the Root-Knot Incidence

The root-knot nematode, *Meloidogyne* spp., has a polyphagous nature in attacking almost all the economically important crops. The root-knot formation has a great significance in the disease development and thus, may prove to be an important parameter in estimating the disease incidence. The incidence of the disease caused by this nematode has been rated variously. Smith<sup>1</sup> merely counted the number of galls in the infected plants and prepared an index based on the percentage of galls, to express the disease development. More or less similar methods, based on visual observations, were used to express the severity of disease, by Jones and Nirula<sup>2</sup>, Khan *et al.*<sup>3</sup> and Mishra and Prasad<sup>4</sup>, without taking into account the dimensions or the mass of the galls, although the severity of the disease depends on the mass rather than the number of galls on the roots.

In the proposed method, the disease incidence is expressed in terms of knot-root ratio, based on the fresh weight of the whole root system of nematode-infected plants and that of the root portions transformed into knots.

*Procedure.*—The inoculated/infected plants were uprooted and washed thoroughly to remove the adhering soil particles. The water particles, adhering to the roots due to washing, were removed using blotting sheets. The roots were then examined for the presence of root-knots. The whole root system was weighed. The visible root-knots of varying size (from minute to large size) were removed under a stereoscopic dissecting microscope, by cutting the knotted portions. The isolated knotted portions of the roots were weighed. The weight of the infected tissue (knots) per g of root was calculated. The results were expressed as the mean values of randomized replicates, in terms of knot-root ratio.

The present quantitative technique is most simple and exact particularly for root-knot, and further, it yields quick results with the least efforts, as it does not involve any cumbersome measurements of the individual root or knot, nor does it need any histological analysis to find out the different stages of nematode development.

### Effect of Climate on the Variation in Electro-Chemical Properties of Natural Humic Acids

Natural humic acid isolated from (1) Dehradun forest soil (pH 5.6), (2) Ooty non-forest acid soil (pH 4.7), (3) Bangalore red soil (pH 4.9) and (4) Nagpur black soil (pH 7.2) was subjected to potentiometric titration. The Nagpur soil humic acid showed greater buffer capacity upto pH 7, indicating abundance of COOH groups while the Ooty soil humic acid showed strong buffering beyond pH 8 showing the presence of phenolic OH groups. Humic acid from Dehradun and Bangalore soils, however, showed little variation in buffer capacity between different pH ranges (pH 4-7, 7-8 and 8-9). This suggests that the reactions, parent phenol  $\rightarrow$  polyphenol  $\rightarrow$  carboxyl, are occurring in these soils. Thus, the results indicate that the variations in the oxidation status of humic acid are largely dependent on the climatic conditions under which soil formation takes place.

TABLE I  
Alkali required to titrate humic acids upto different pH levels

| Place     | Amount of alkali required<br>(me. per 100 gm humic acid) |            |            |
|-----------|--|------------|------------|
|           | pH 4.0-7.0   | pH 7.0-8.0 | pH 8.0-9.0 |
| Nagpur    | 27.3   | 9.6        | ..         |
| Dehradun  | 10.6   | 7.3        | 9.0        |
| Ooty      | 6.0  | 3.0        | 12.6       |
| Bangalore | 5.6  | 4.3        | 5.0        |

### A New Bacterial Disease on "Varalaxmi" a Hybrid Cotton

"Varalaxmi" cotton, a hybrid (*Gossypium hirsutum* ♀  $\times$  *Gossypium barbadense* ♂) was reported to be suffering from wilt disease. When such samples were examined they invariably showed vascular discolouration either in the form of disjointed streaks or continuous streaks extending

from root region upto the stem. In some of the samples received later, there was hardly any discolouration in the vascular tissue of the stem and taproot, but it was noticed only in secondary and tertiary roots. Transverse sections of such roots did not show any vascular mycelium. From the samples examined, it appeared that plants of any age group are liable for infection.

Isolations from such discoloured vascular tissues, invariably, yielded a bacterial culture on Nutrient agar. Culture obtained from tissue isolation was further purified by dilution-plating, and culture from single well-isolated colony was transferred to sterile distilled water and maintained at 20°C for further studies. This culture was successfully used in artificial reproduction of the disease, by inoculating the injured side roots of 10 days old cotton seedlings, grown in sterile soil.

The bacterium makes dull white, slimy growth on NA. Bacterium is a short rod gram negative, non-acid fast, non-spore forming with a single polar flagellum. Bacterium does not hydrolyse starch, does not produce indole and H<sub>2</sub>S. It does not produce fluorescent pigment on fluorescein medium<sup>1</sup> when observed under ultraviolet light, and makes fluidal opaque irregularly circular colonies, with slight pink colour at the centre on Triphenyl tetrazolium chloride medium<sup>2</sup>.

Based on the morphological, cultural and biochemical characters, the organism under study has been identified as *Pseudomonas solanacearum* E.F.Sm., a new record on cotton. Studies are in progress regarding its relationship with other isolates of *P. solanacearum* from Potato, Tomato and Eggplant.

The authors are grateful to Dr. H. C. Govindu, Senior Professor, UNDP, for providing facilities. Dept. of Plant Pathology, V. V. SULLADMATH. Univ. of Agril. Sciences, R. K. HEGDE. Bangalore 560024, B. G. PATIL KULKARNI. February 12, 1975. P. C. HIREMATH.

### Effect of Crowding on the Nymphal Duration of *Hieroglyphus nigrореpletus* Bol. (Orthoptera: Acrididae)\*

*Hieroglyphus nigrореpletus* Bol. (Phadka grasshopper) is a pest of rice, millet, sugarcane and other crops in India. This pest is of considerable importance in the Tarai regions of Uttar Pradesh because of their abundance in this part of the country. The present writers consider it as 'monsoon enemy of man' because they appear just after the

first monsoon showers in their breeding areas and start feeding voraciously on the seedlings of the crops and chop them off. Roonwal (1945) has studied the seasonal history of this pest at Banaras (Varanasi) but much attention has not been paid to the effect of crowding on the nymphal duration of this pest. Norris (1952) could not find any significant difference in the nymphal duration of *Schistocerca gregaria* Forskal when reared under isolated as well as crowded conditions, but the present writers have recorded a marked effect of crowding on the nymphal duration of *H. nigro-repletus* Bol. The nymphs of *H. nigrorepletus*, when reared collectively, completed their development in a shorter period of time as compared to those reared individually. This behaviour is of vital importance to this pest as it retains a solitary nature throughout its life-cycle.

The experiment on the crowding effect on nymphal duration was carried out with fifty freshly hatched nymphs which were reared at  $32^{\circ}\text{C} \pm 2^{\circ}\text{C}$  in each glass jar ( $15 \times 10$  cm). At the same temperature only ten hoppers were reared in a glass jar of the same size. Obviously the former batch of hoppers got less space in terms of per hopper space as compared to the latter batch of hoppers. Nymphs reared in crowded conditions took 35 to 45 days; but those reared under isolated conditions took 75.5 to 80.5 days in completing their development. The average nymphal duration under crowded and isolated condition has, therefore, been recorded as 40.0 and 80.0 days respectively.

Thanks are due to Prof. M. Shafi, D.A.P. and Prof. Reyat Khan, for their interest and encouragement.

#### Reduction in Oil Content of Yellow Mosaic Infected Soybean Seeds

Like other plants soybean is afflicted with a number of virus diseases which cause disturbances in the host physiology. In the present study, the

yellow mosaic disease of soybean, possibly caused by Mung bean yellow mosaic virus, was found to reduce the oil content of seeds in all the varieties tested.

Six varieties of soybean, viz., Bragg, Clark-63, Lee, Amsoy, Picket and Local-2 were selected for oil estimation. For each variety two lots each of 20 seedlings were taken. One lot was treated with white flies (*Bemisia tabaci* Gennadius) fed on diseased soybean leaves. The other lot was left healthy. The plants were kept in insect proof conditions. When plants attained maturity their seeds were collected separately and their oil content estimated, using Soxhlet's method. The data are presented in Table I.

TABLE I  
Oil content in healthy and yellow mosaic infected seeds of different varieties of soybean (data based on oil extracted from 4g seeds under each treatment)

| Varieties | Per cent oil content |          |
|-----------|----------------------|----------|
|           | Healthy              | Diseased |
| Bragg     | 25.3                 | 17.6     |
| Clark-63  | 26.1                 | 17.4     |
| Lee       | 25.5                 | 14.3     |
| Amsoy     | 25.6                 | 16.6     |
| Picket    | 25.8                 | 16.0     |
| Local-2   | 21.4                 | 11.8     |

The seeds from diseased plants contained less oil than the seeds from healthy plants. The varieties relatively more susceptible to the disease showed more marked reduction in oil content. Lee and Local-2 had maximum reduction while Bragg had least.

Harris *et al.*<sup>1</sup> reported that soybean infected with chlorotic mottle virus (soybean strain) had a reduced oil percentage in the seeds. Demski *et al.*<sup>2</sup> reported that tobacco ring spot virus infection reduced the palmitic, linoleic and linolenic acid proportions of the oil while stearic and oleic acids increased in soybean plants (Cv. Lee).

The author is thankful to Prof. K. S. Bhargava for providing necessary laboratory and library facilities.

## REVIEWS AND NOTICES OF BOOKS

---

---

**Modern Microscopy—Elementary Theory and Practice.** By C. F. A. Culling. (Butterworths and Co., Ltd., 88, Kingsway, London, WC 2 B 6AB). 1974. Pp. xii + 148. Price £ 1.50.

This book on *Modern Microscopy* by C. F. A. Culling (Butterworth and Co., Publishers Ltd., 1974) deals with theoretical principles and practical aspects of a wide range of microscopes.

There are, in addition to the introduction, 12 chapters. The first chapter exclusively deals with the various optical and mechanical aspects of a compound microscope, the illumination, setting up the microscope, and finally the micrometry. An additional feature of this chapter is the treatment of lenses and their aberrations which is an asset to every microscopist. In the second chapter the author briefly describes and recommends the use of the comparison microscope for comparing by direct observation of the two specimens instead of relying on human memory for this comparison. The brief third and fourth chapters deal respectively with the low-power dissecting microscope and the dark-ground microscope. The next two chapters, namely the fifth and sixth, introduce the concepts of fluorescence and discuss the fluorescent microscope techniques. Autofluorescence, fluorescent staining and fluorescent antibody techniques are treated rather elaborately. In the seventh chapter the author treats some aspects of polarisation as needed for the use of a polarising microscope. The next chapter deals with the phase contrast microscope. In chapters nine and ten the interference contrast microscope (Nomarsky) and the interference microscope are well presented. Brief and succinct in the presentation, these two chapters deliver the necessary information on the fundamental principles, setting up and using the microscopes.

While dealing with photomicrography in chapter eleven, the author has considered at length on some essential prerequisites for good image such as elimination of vibration, use of camera with and without lens, light sources, magnification and resolution and use of colour filters to obtain contrast. Electron microscopy forms the subject-matter of the last chapter. A brief theory and construction of an electron microscope is followed by details on the techniques of preparation of tissue sections for examination with the microscope. Staining methods and preparation of electron microscope grids are also included.

This booklet is an asset to the libraries and students. Elementary theory and principles involved in each microscope, methods of preparing materials, and staining techniques have been presented in a lucid and detailed manner. As the author claims, this book truly meets the needs of students and research workers alike. The book is recommended to students of biology, chemistry, physics, pathology, and laboratory technologists.

**Annual Review of Biophysics and Bioengineering (Vol. 3).** Edited by L. J. Mullins, William A. Hagins, Lubert Stryer and Carol Newton. (Annual Reviews, Inc., 4139 El Camino Way, Palo Alto, California 94306), 1974. Pp. 401. Price: U.S.A. \$ 12.00; Foreign \$ 12.50.

The volume contains a number of reviews on various different branches of biophysics and bioengineering, and the scope of the volume is best illustrated by giving the titles of the different articles, which are the following: Kinetics of allosteric Enzymes; Some Applications of Calorimetry in Biochemistry and Biology; Structure of Photoreceptor Membranes; Protein Model Refinement Based on X-Ray Data; The Properties of Water in Biological Systems; Conformational Changes in DNA Molecules; The Structure and Spectra of the Chromophore of the Visual Pigments; Rotational and Translational Diffusion in Membranes; Thermodynamic Relationships in Mitochondrial Oxidative Phosphorylation; Collagen as a Biomaterial; Automata and Biology; The Analysis of Convection and Diffusion in Capillary Beds; Freezing Injury and its Prevention in Living Cells; and Scintillation Scanning of the Brain. The two articles of special interest to the reviewer were the one by L. H. Jensen on protein structural refinement and the one by Stenzel, Miyata and Albert L. Rubin on collagen as a biomaterial.

Jensen's article describes the refinement of the crystal structures of a number of proteins using X-ray data and standard techniques of Fourier and least-squares refinement. It is interesting to note that in the case of Rubredoxin, the R-value came down from nearly 0.4 to 0.126. As a result, several of the side-group atoms came out very prominently and could be readily located. However, in the case of cytochrome *c*, the protein molecule itself did not refine, but only the solvent

molecules could be located. The method is, therefore, of great value in small proteins and has still to be worked out in the case of larger protein molecules.

The chapter on collagen as a biomaterial starts with the biochemical and biophysical properties of collagen, in which the primary structure, cross links and the action of collagenase on collagen are treated. This is followed by an account of the biological properties of collagen and the clinical applications of various types of collagenase material such as collagen heterografts, reconstituted collagen, extruded collagen fibres, collagen membranes and films, and collagen gels and sponges. The article is brief, but contains a valuable collection of information to the bioengineer for using collagen for "eye surgery, skin and bone replacement, blood vessel and heart valve implantation, dialysis and drug delivery and possibly result in the restructuring of normal tissues".

The volume as a whole is highly informative and useful, and is strongly recommended to every biological library.

G. N. RAMACHANDRAN.

**The Red Shift Controversy.** By George B. Field, Halton Arp and John R. Bahcall. (W. A. Benjamin Inc., Advanced Book Programme, Reading, Massachusetts, U.S.A.), 1973. Pp. xvi + 324. Cloth \$19.50; Paper \$11.00.

The Frontiers in Physics Series concerns itself with the problem of communicating in a coherent fashion the recent exciting developments in the active new fields of physics. In this task, the present book has succeeded admirably. It presents a quick survey of the problems raised by the large Doppler shifts and the large apparent luminosities of quasi stellar objects (quasars) and their cosmological implications.

Since Hubble's observation in 1929 of a linear relationship between the distance of a far-off galaxy and the Doppler red shift interpreted as a velocity of recession from us, the model of an expanding universe has been firmly accepted with the Hubble's law as the observational evidence. The discovery of quasars in the early sixties has thrown up a problem. If their large red shifts are interpreted to mean that they are at very great distances, then their high apparent luminosity implies an unusually large intrinsic luminosity and energy content for the quasar. On the other hand if an acceptably large intrinsic luminosity is assumed and the apparent luminosity used to infer the distance of the quasar from us, then there is a

breakdown of the Hubble's law. This present debate in the field of cosmological studies is summarized in the book, with Dr. Arp stating the case for the breakdown of the Hubble's law for the quasars, Dr. Bahcall stating the case for the unusual luminosity of the quasars and Dr. Field acting as the moderator.

The book is based on the discussion held at the American Association for Advancement of Science in December 1972. The book has been released in May 1974. Apart from the survey articles of Arp and Bahcall, the book includes reprints of about 30 significant papers published on the subject. Inevitably newer observations will render any book out of date, particularly a book of this type. However there is no doubt that, like another astronomical phenomenon namely the meteor, the book will illumine the field for a while and fade away from view afterwards, having fulfilled its destined role.

P. S. NARAYANAN.

## ANNOUNCEMENTS

### Award of Research Degrees

Utkal University, Bhubaneswar, has awarded the Ph.D. degree in Mathematics to Shri Umakanta Mohapatra for his thesis entitled "Flow and Heat Transfer in Visco-elastic Liquids".

The M.S. University of Baroda has awarded the Ph.D. degree in Biochemistry to Shri Shashikant Jagannath Tarwadi for his thesis entitled "Studies on Algal Bacterial Symbiosis in High Rate Oxidation Ponds using *Oscillatoria* Spp."; Ph.D. degree in Biochemistry to Shri Chandrakant Mohanlal Upadhyay for his thesis entitled "Effects of Dietary Variations on Bone Composition in Rats"; Ph.D. degree in Psychology to Shri Prasant Kumar Gangopadhyay for his thesis entitled "Social Intelligence and Its Relationship with Abstract and Mechanical Intelligence".

### Books Received

*Radiometric Methods of Exploration.* By V. L. S. Bhimasankaram. (Centre of Exploration Geophysics, Osmania University, Hyderabad 500 007), 1974. Pp. xvi + 212. Price Rs. 20.00; \$4.00 (postage extra).

*Indian Journal of Earth Sciences* (Vol. 1, No. 1). (Indian Society of Earth Sciences, Department of Geology, Presidency College, Calcutta 700012), 1974. Pp. ix + 130. Price: Annual Subscription: India, Rs. 40.00; U.S., \$10.00; £4.00; Personal Subscription in India: Rs. 20.00.

## INFORMATION TO CONTRIBUTORS

**CURRENT SCIENCE** is the Premier Science Fortnightly of India published by the Current Science Association, Bangalore and issued on the 5th and 20th of each month. All material intended for publication in **CURRENT SCIENCE** and books for review should be addressed to the Editor, *Current Science*, Raman Research Institute, Bangalore-560006.

The following types of Scientific Communications will be considered for publication :

- (i) Review articles on topics of major current interest not exceeding 4,000 words;
- (ii) Original Research Papers—not exceeding 2,000 words;
- (iii) Letters : These are brief reports of research of unusual and wide interest—they should not exceed 700 words in general;
- (iv) Short Scientific Notes—not exceeding 250 words.

Articles and papers should include a short abstract at the beginning.

References are indicated by superscripts in the text. The style of references should be *Journal* : The names of the authors, the journal, year, volume and page.

*Book* : Authors names, the title of the book, name and location of the publishers, year and page.

"Personal Communications" and "Unpublished Work" do not go into references and should be incorporated in the text. Acknowledgements should be brief.

Statements that the work is contribution No..... of the Institute, declarations that the Director has authorised publications, etc., are not printed.

"Series" papers are discouraged.

Manuscripts, to be submitted in duplicate, should be typewritten in double space on one side of the paper, carefully revised and in final form for printing. Illustrations should be minimum in number, drawn in black and white with Indian ink on bristol board. Figures are usually reduced to one column width, and the originals should be about twice their final size.

No reprints are supplied gratis, but can be had on request at cost per V.P.P.

Business correspondence, remittances, subscriptions, advertisements, reprints, exchange journals, etc., should be addressed to the Manager, Current Science Association, Raman Research Institute, Bangalore-560006.

---

### Subscription Rates :

Institutions : India Rs. 84.00 ; Foreign Rs. 150.00 ; \$ 20.00 or £ 8.00.

Individuals : India Rs. 24.00 ; Foreign £ 3.50 ; \$ 8.00.

# CURRENT SCIENCE

*Fortnightly Journal of Research*

Issued on the 5th and 20th of each month

## IMPORTANT NOTICE TO SUBSCRIBERS OF THE JOURNAL

As you are aware CURRENT SCIENCE has been coming out regularly on the due dates as above with the kind co-operation of you all.

On account of the sharp increase in the cost of quality paper used for the Journal, increase in rates of block making materials, increase in postal rates and the increase in the establishment charges it has become impossible for the Association to issue the Journal, unless the subscription rates are put up.

The Working Committee of the Association has reluctantly decided at its last meeting, to enhance the subscription of CURRENT SCIENCE with effect from 1st January 1975 for institutions :

India Rs. 84/- Foreign Rs. 150.00 \$ 20.00 or £ 8.0.0

The subscription rates for individual subscribers however will remain the same as now.

The continued co-operation of our subscribers is requested.

# MIXED LIGAND COMPLEXES OF COBALT (III) WITH N, N'-ETHYLENEDIAMINE-BIS (SALICYLIDENEIMINE) AND BIDENTATE MONOBASIC NO AND OO DONOR LIGANDS

A. SYAMAL AND V. D. GHANEKAR

Department of Chemical Technology, The University of Bombay, Matunga Road, Bombay 400019

## ABSTRACT

The syntheses of several new cobalt (III) mixed ligand complexes containing dibasic ONNO donor quadridentate ligand salen [where salen H., = N, N'-ethylenediaminebis (salicylideneimine)] and bidentate monobasic NO or OO donor ligands such as quinaldinic acid, N-phenylsalicylaldimine, methylacetoacetate, ethylacetoacetate, and 2-hydroxy-naphthaldehyde are described. The complexes are characterised by conductance measurements, electronic spectra, infrared spectra, magnetic susceptibility and molecular weight measurements. The complexes are green in colour, monomers, diamagnetic and non-electrolytes. In these mixed ligand complexes salen adopts an unusual nonplanar twisted configuration and the bidentate ligand occupies two *cis* positions. The electronic spectral and magnetic data indicate distorted octahedral nature of the complexes. The electronic spectra of the complexes in chloroform and pyridine are quite different. In pyridine the complexes undergo rearrangement and two pyridine molecules enter the coordination sphere with simultaneous removal of the bidentate ligand.

## INTRODUCTION

THE syntheses and single crystal X-ray structure determination of cobalt (III) heterochelates containing nonplanar quadridentate ligand salen and bidentate OO donor ligands  $\beta$ -diketones and salicylaldehyde have been reported<sup>1-4</sup>. We have extended these studies to NO donor ligands. In this communication we report the synthesis and characterisation of such heterochelates containing bidentate NO donor monobasic ligands quinaldinic acid and N-phenylsalicylaldimine. We also report several new heterochelates containing OO donor bidentate monobasic ligands such as methylacetoacetate, ethylacetoacetate and 2-hydroxynaphthaldehyde.

## EXPERIMENTAL

**Materials and Methods.**—Cobalt (II) chloride hexahydrate, salicylaldehyde, ethylenediamine, aniline, pyridine and nitrobenzene were from Sarabhai M. and Co. Methylacetoacetate, ethylacetoacetate, quinaldinic acid and 2-hydroxynaphthaldehyde were obtained from Fluka AG, Switzerland.

The electrolytic conductance measurements were carried out with a Radelkis type OK 102/1 conductivity bridge and a dip type of cell. The magnetic susceptibility measurements were carried out at room temperature by the Gouy method using  $\text{Hg}[\text{Co}(\text{NCS})_4]$  as a calibrant. Infrared spectra were recorded in KBr pellets on a Perkin Elmer Model 21 infrared spectrophotometer. Each spectrum was calibrated with a polystyrene film. Electronic spectra were obtained with the Beckman DK2 recording spectrophotometer using 10 mm matched quartz cells. Molecular weights were determined by the freezing point method in nitrobenzene.

N-phenylsalicylaldimine was prepared by refluxing salicylaldehyde and aniline in ethanol for half an hour and subsequent cooling. Co(salen) was prepared according to the method of Diehl and Hach<sup>5</sup>. This was oxidised to the corresponding cobalt (III) complex,  $[\text{Co}(\text{salen})]_2\text{O}_2$  by passing air through a chloroform suspension of Co(salen) for 3 hr.

Preparation of  $[\text{Co}(\text{quinaldinic acid})(\text{salen})]\text{H}_2\text{O}$ : Quinaldinic acid (0.53 g) was dissolved in 15 ml of absolute alcohol. This was added to a suspension of Co (salen) (1 g, 0.003 mole) in 20 ml ethanol. The mixture was heated on a water bath for 1 hr and filtered after cooling to room temperature. The residue was dissolved in minimum amount of 1 : 1 ethanol : chloroform mixture, filtered and the filtrate was partially evaporated on a water bath. The separated green precipitates were suction filtered, washed with alcohol followed by ether and dried under vacuum at room temperature. Yield = 20%. This complex cannot be obtained in pure form starting from  $[\text{Co}(\text{salen})]_2\text{O}_2$ .

All other complexes were prepared by following the general procedure described below:

$[\text{Co}(\text{salen})]_2\text{O}_2$  (1 g) was suspended in 20 ml of absolute alcohol. To this an ethanolic solution of the appropriate ligand (0.0030 mole in 15–20 ml) was added and the mixture was heated on a water bath for 1 hr and cooled to room temperature. In the case of methylacetoacetate and ethylacetoacetate, the mixture was not heated but kept at room temperature for 2 hr with occasional stirring. This was filtered and the residue was treated similarly as described under the quinaldinic acid complex. In the case of methylacetoacetate and ethylacetoacetate the partial evaporation of solvents was done under a fan at room temperature. The yield varied from 25–40%.

### RESULTS AND DISCUSSION

The bidentate mono basic ligands react with [Co(salen)]<sub>2</sub>O<sub>3</sub> in ethanol medium at the temperature of steam bath. Methylacetoacetate and ethylacetoacetate react with [Co(salen)]<sub>2</sub>O<sub>3</sub> in ethanol even at room temperature. Apparently the complexes were formed by breaking the  $\mu$  oxygen bridge in [Co(salen)]<sub>2</sub>O<sub>3</sub> in the presence of the bidentate ligand. Our attempt to prepare heterochelate complex with NO donor ligand picolinic acid by the reaction of this ligand with [Co(salen)]<sub>2</sub>O<sub>3</sub> in ethanol was unsuccessful and we isolated the red cobalt picolinate as the major product. But in the case of other bidentate ligands we did not notice the formation of homochelates and the desired heterochelates were the major products. The complexes are non-electrolytes ( $\Lambda_{\text{m}} = 1.6\text{--}2.7 \text{ ohm}^{-1}\text{cm}^2 \text{ mole}^{-1}$ ) in methanol. The molecular weights in the nitrobenzene indicate that the complexes are monomer in this solvent (see Table I). The magnetic susceptibility measurements indicate that the complexes are diamagnetic as expected for d<sup>6</sup> cobalt (III) complexes of octahedral symmetry.

The  $\nu(\text{OH})$  stretch of the ligand salenH<sub>2</sub> at 2600 cm<sup>-1</sup> (ref. 6) is absent in the complexes indicating coordination through the phenolic oxygen atoms. But the heterochelate complex with quinaldinic acid has a medium intense  $\nu(\text{OH})$  band at 3300 cm<sup>-1</sup> in accordance with the elemental analysis of the complex. This water molecule in [Co (quinaldinic acid) (salen)] H<sub>2</sub>O is the water of crystallisation, as the coordinated water usually exhibit  $\nu(\text{OH})$  band around 3100 cm<sup>-1</sup> (ref. 7). In some of our complexes the carbonyl stretching

vibrations occur at lower frequencies in comparison to those of the free ligands. This lowering of the  $\nu(\text{C=O})$  bands is indicative of the oxygen coordination of the bidentate ligands. The  $\nu(\text{C=N})$  and the conjugated phenyl ring vibrations of salenH<sub>2</sub> shifts to higher frequencies in the complexes and this observation is in line with the infrared spectra of other metal complexes of salenH<sub>2</sub><sup>6</sup>.

We have recorded the electronic spectra of the complexes in chloroform and pyridine. The complexes exhibit three bands at around 16,000, 25,000 and 39,000 cm<sup>-1</sup> (see Table II). The first band

at  $\sim 16,000\text{ cm}^{-1}$  is assigned to the  ${}^1A_{1g} \rightarrow {}^1T_{1g}$  transition and the second band at  $\sim 25000\text{ cm}^{-1}$  is assigned to the  ${}^1A_{1g} \rightarrow {}^1T_{2g}$  transition coupled with the metal-ligand transition. The third band at  $\sim 39,000\text{ cm}^{-1}$  is assigned to the transitions in the ligand and/or charge transfer transitions. We have noticed that the electronic spectra of the complexes in chloroform and pyridine differ appreciably. The band at  $\sim 16,000\text{ cm}^{-1}$  observed in chloroform solution is missing in the electronic spectra of the complexes in pyridine. It seems that this band is moved to higher energy and is covered underneath the intense transitions. The cause of this marked difference in the electronic spectra is attributed to the pyridine coordination with the simultaneous removal of the bidentate ligand from the coordination zone<sup>4</sup>.

## EFFECT OF SUNLIGHT ON THE VIABILITY AND CHROMOGENESIS OF THREE WIDESPREAD BACTERIA

PARIMALA VARADARAJ AND J. V. BHAT

Microbiology and Cell Biology Laboratory,

Indian Institute of Science, Bangalore, and Kasturba Medical College, Manipal

#### ABSTRACT

Viability and chromogenesis of *S. marcescens*, *P. aeruginosa* and *S. aureus* in water, milk, and soil have been studied over a period of 180 days. Viability in darkness and diffused light has been shown to be longer than under sunlight. The effect of sunlight, diffused light, and darkness on the colour of the pigment produced by these bacteria has been reported.

#### INTRODUCTION

FROM the previous study on the viability of *Serratia marcescens* in 5 g aliquots of soil inoculated with approximately 50 million cells, it was concluded that the organism could not survive in the air-dry state of the soil under the influence of direct sunlight for 30 days, though it did survive under the semi-saturated and water-logged states of soil for the same period of exposure. Under diffused light and in darkness, however, the organism survived for 30 days in the dry soil, although a discernible difference was observed in its morphology and pigmentation on nutrient agar. On the other hand, samples of soil with the organism incubated under darkness gave good growth of the organism on nutrient agar even in the dry state and luxuriant growth as well as normal pigmentation were witnessed from the semisaturated and the water-logged samples of soil.

*Pseudomonas aeruginosa* inoculated (about  $50 \times 10^6$ ) in the dry soil<sup>2</sup>, unlike *S. marcescens*, could survive 30 days exposure to direct sunlight; the exposure, however, affected its pigmentation both under the direct light and diffused light. Incubation of soil under darkness did not have such effect especially under humid conditions which favourably influenced both viability and pigmentation in that the semi-saturated soil kept under diffused light yielded fairly well pigmented growth whereas the water-logged soil gave both normal growth and characteristic pigmentation.

Like *Pseudomonas aeruginosa*, *Staphylococcus citreus* also survived 30 days exposure to all light-weather conditions, but presented variable picture of growth and pigmentation<sup>3</sup>. It was in this context that viability and pigmentation of the two rod-shaped chromogenic bacteria and a strain of *Staphylococcus aureus* (instead of *S. citreus* used

in the earlier study) were considered of interest for longer periods of exposure under the different light-weather conditions in the three media, water, milk and soil. The results of a prolonged study, extending over 6 months, are presented in this paper.

#### MATERIALS, METHODS AND RESULTS

Cultures of *Serratia marcescens*, *Pseudomonas aeruginosa* and *Staphylococcus aureus* used in the experiments were those derived from the stock maintained in the Microbiology and Pharmacology Laboratory for nearly two decades. The cultures were first tested for their purity, pigmentation in particular, and other characteristics in general. Pigmentation-wise, the three bacteria were respectively dark red (Hue 10 R 3/6), dark olive green (Hue 5 Y 3/2) and yellow (Hue 5 Y 8/6) as per Munsell Soil Color Charts<sup>4</sup>.

Skimmed milk, obtained from the whole milk supplied in bulk by the Hessaraghatta dairy farm, water from the tap (Bangalore City supply) and soil from the reddish garden loam soil (unsieved, pH 6.9) were the other materials used, in the experiment after sterilization in the autoclaves. The sterility of these materials was tested by the routine sterility tests before their inoculation with the three cultures.

The liquid media were distributed in 25 ml aliquots in nine 100 ml Erlenmeyer flasks and in 10 ml quantities in nine test tubes (6 × 5/8") and the soil in 50 g lots and 20 g lots in flasks and test tubes respectively. Into flasks was inoculated 1 ml of young liquid cultures (3 flasks and 3 test tubes for each culture) and in tubes the inoculum was

and incubated at the three environmental conditions for observation of growth and pigmentation. Similar tests were performed in water and soil with the three bacteria mentioned in the text. The experimental set-up would become clear from the scheme.

#### Scheme followed for testing viability and pigmentation

Milk: Culture. *S. marcescens* (Subcultured on N. agar in all cases)

| Exposed to | Incubated in sunlight (L) |
|------------|---------------------------|
| sunlight   | diffused light (DL)       |
|            | darkness (D)              |
| Exposed to | sunlight (L)              |
| diffused   | diffused light (DL)       |
| light      | darkness (D)              |
| Kept in    | sunlight (L)              |
| darkness   | diffused light (DL)       |
|            | darkness (D)              |

Viability was recorded by general appearance of growth on the agar slant and no particular attention was paid to ascertaining the extent of growth. Pigmentation was noted and, where possible, the colour was compared to "Munsell colour Chart" and the colour recorded. Table I presents the viability in days and Table II the colours of the three organisms on nutrient agar after incubation thereof in the three media under the different light weather conditions. The pigmentation Hues reported in Table II correspond to those recorded for cultures which survived the incubation period in days as shown in Table I.

TABLE I  
Viability in days in milk, water and soil

| Incubation<br>Organisms | Milk |    |     | Water |    |    | Soil |    |     |

| <i>S. aureus</i>        | ..   | 10 | 120 | 120   | 10 | 90 | 120  | 30 | 180 |
| <i>S. marcescens</i>    | ..   | 10 | 120 | 120   | 10 | 90 | 120  | 30 | 180 |

L = Sunlight.

DL = Diffused light.

D = Darkness.

pipetted in 0.1 ml aliquots. The contents were well mixed and one flask and one test tube of each of the three natural media were incubated respectively in direct sunlight, in diffused light and in a completely darkened room.

At intervals, a loopful (small quantity) of the inoculated soil, milk or water was inoculated on 9 slants of nutrient agar for each of the culture

It will be clear from the results that *S. marcescens* not only survived 180 days in soil under both darkness and diffused light but retained its original Hue 10 R 3/6, deemed as dark red. The organism lived however for only 120 days in milk under diffused light and darkness as it did in water only in darkness. It is extremely interesting to note that this organism continued to synthesise its pigment

of original Hue in water for 120 days, whereas the Hue got changed to red (10R 4/6) in milk kept under diffused light and darkness. This red colour was retained in water kept in DL, though the organism survived under this condition for only 90 days.

In direct sunlight this organism survived in damp soil for as many as 30 days, an observation made for another strain long time back<sup>1</sup>. In both milk

and water, under direct light, the organism however could not live longer than 10 days.

Both *P. aeruginosa* and *S. aureus*, like *S. marcescens*, survived for 10 days only in sunlight when suspended in water or milk. In other respects also their viability was similar to that shown by *S. marcescens*. However, *P. aeruginosa* seems to retain its pigmentation property better in that it continued to elaborate its dark olive (5Y 3/2) in milk under

darkness, and in water and soil under both darkness and diffused light. Likewise, *S. aureus* displayed the ability to retain its pigmentation property in all media under darkness and diffused light only: under direct sunlight, it changed from yellow to pale yellow.

The viability and pigmentation studies on the three bacteria thus reveal the extent to which they can resist the sterilising effect of sunlight and explains their widespread distribution throughout the universe.

### IN VITRO INFLUENCE OF SCORPION VENOM ON THE ENZYME SYSTEMS OF SCORPION, *HETEROMETRUS FULVIPES*

CH. RADHAKRISHNAMURTHY, Y. PRAMEELAMMA, A. V. GOVARDHANAREDDY AND K. S. SWAMI

Department of Zoology, S.V. University, Tirupati 517502, India

#### ABSTRACT

Influence of scorpion venom on the enzyme systems of its own tissues was studied. Aminotransferases and aldolase activities were unaffected in the hepatopancreas. Similar results excepting a decrease in alanine aminotransferase in neuronal mass was noticed. Both the nonspecific acid and neutral protease activities were enhanced by the addition of venom in hepatopancreas and neuronal mass. The results are discussed in terms of ammonia production and ammonogenic coma during venom toxicity.

#### INTRODUCTION

THE cannibalistic behaviour in the scorpions, reported earlier<sup>1</sup>, prompted us to study the biochemical changes in the scorpion tissues during the paralysed state of the animal when the venom from the opponent is injected into it. In the present study we have selected representative enzymes from glycolytic pathway, protein and amino acid metabolism.

#### MATERIALS AND METHODS

Scorpions were collected from local hilly terrain and were adapted to the laboratory conditions. They were kept in separate glass jars to prevent cannibalism amongst them and were fed daily with cockroaches.

Venom was collected from scorpions as reported earlier<sup>2</sup> excepting that distilled water was used instead of K-Na phosphate buffer. The protein content of the venom was adjusted to 500 µgm/ml.

Hepatopancreas and the cephalothoracic nerve mass along with ventral nerve cord (referred hitherto as neuronal mass) were isolated from the scorpions. Tissue homogenates (10% for hepatopancreas and 5% for neuronal mass) were prepared either in 0.25 M sucrose solution or in distilled water at 4° C and were centrifuged at 2,000 rpm for 15 min. The supernatants were collected for enzyme assay.

Aspartate aminotransferase (L-Aspartate: 2-α-oxoglutarate aminotransferase, E.C.2.6.1.1.) and alanine aminotransferase (DL-Alanine: 2-α-oxoglutarate aminotransferase E.C.2.6.1.2.) were assayed<sup>3</sup>. Aldolase activity was determined by the method of Burns and Bergmeyer<sup>4</sup>. Non-specific acid and neutral proteases were assayed<sup>5</sup>.

The experimental tubes contained 0.2 ml of venom corresponding to 100 µgm of protein whereas the control tubes contained the same volume of distilled water. All the protein determinations were made by the method of Lowry *et al.* (1951)<sup>6</sup>. Each enzyme was assayed in six different animals and in duplicates and the results were expressed as mean of these values.

#### RESULTS AND DISCUSSION

The scorpion venom seems to induce differential effects on the enzyme activity levels in its hepatopancreas and neuronal mass (Table I). The activity levels of aldolase are comparatively less altered than the other enzymes on the addition of venom suggesting that glycolysis as represented by hexose cleavage is least sensitive in both the tissues studied. The venom of *Buthus minax* was known to induce hyperglycemia which was believed to be due to elevated glycogenolysis or gluconeogenesis<sup>7</sup>. Further, the venom of *Centruroides sculpturatus* is known to act at acetyl CoA level<sup>8</sup>. Thus the venom

effects do not involve glycolysis. The venom of *H. fulvipes* was found to inhibit succinate dehydrogenase activity in its neuronal mass<sup>2</sup> and decreased the respiratory rate in cockroach<sup>9</sup> indicating that one of the targets of the venom action is the operation of the citric acid cycle retaining the usual glycolytic rate so as to meet the energy demands.

Though the venom has been shown to be devoid of proteolytic activity<sup>10</sup>, it has elevated the acid and neutral protease activity levels in both the hepatopancreas and neuronal mass (Table I) probably

Thus the venom effects are at the aerobic segment of the carbohydrate metabolism as represented by lowered succinate dehydrogenase activity. The lowered metabolism of keto acids in citric acid cycle and elevated glutamate dehydrogenase indicate the possibility of ammonia toxicity.

#### ACKNOWLEDGEMENT

 N.S., Not significant.

increasing the amino acid level. The oxidative deamination of amino acids are considered to be liberating ammonia since the glutamate dehydrogenase activity was reported to increase<sup>2</sup>. Since aminotransferase activity levels were also least affected or inhibited by venom (Table I) the accumulated ammonia may result in decreased neuronal activity either directly or indirectly (draining out the keto acid metabolites of the citric acid cycle) thus restricting the energy generation.

The greater reduction of alanine aminotransferase activity in the neuronal mass in comparison with the hepatopancreas by the venom indicated lower pyruvate feeding from the amino acid source into the citric acid cycle. Unlike the alanine aminotransferase, the aspartate aminotransferase activity level was less affected by the venom (Table I) in both the tissues suggesting that the feeding of oxaloacetate or  $\alpha$ -ketoglutarate is unaltered during venom toxicity.

# RADIOCARBON DATES OF NEOLITHIC-CHALCOLITHIC SAMPLES

D. P. AGRAWAL AND SHEELA KUSUMGAR

Physical Research Laboratory, Ahmedabad 380009

**W**E report below the  $^{14}\text{C}$  dates from the neolithic sites of Bihar, Karnataka and some Harappan and allied sites of Rajasthan, Punjab and Gujarat. Experimental procedures are given very briefly here, for details see Kusumgar *et al.*, 1963; Agrawal *et al.*, 1971, Agrawal and Kusumgar, 1973.

Extraneous matter in the form of rootlets and sticking soil, etc., were removed manually. For the removal of humic contamination, alkali pretreatment was given to all the samples except TF-576, -748 and -699. Acid leaching was used to get rid of soil carbonates, if any. Samples were counted in the form of methane gas in gas proportional counters. NBS oxalic acid was used as modern reference standard.

For each sample two B.P. dates are given. The first is based on the half-life value of 5568 yrs and the second, within parenthesis, is based on 5730 yrs value. The same half-life based dates should be used for all intercomparisons. A.D. 1950 should be used as reference year for conversion of B.P. dates to A.D./B.C. scale.

## GENERAL COMMENT ON DATES

It is interesting to note that Bara is not a pre-Harappan site but even later than Kalibangan in point of time. This shows that some of the so-called pre-Harappan cultures were in fact rural cultures which continued without much change even after the end of the Harappa Culture. The antiquity of Chirand now extends back to c. 1700 B.C., though some neolithic backwaters of Bihar continued upto the I millennium B.C. Hallur dates (TF-570 and -576), if confirmed from other sites, may extend the antiquity of iron in the south to the beginning of the I millennium B.C.

## ACKNOWLEDGEMENTS

We are thankful to Ss. R. V. Krishnamurthy and R. K. Pant. for help in the preparation of the manuscript.

## $^{14}\text{C}$ DATES WITH SAMPLE DESCRIPTIONS

### Bara, Punjab, India

Bara (Lat.  $30^{\circ} 56' \text{ N.}$ , Long.  $76^{\circ} 32' \text{ E.}$ ) is situated in the Rupar District of Punjab. Bara excavations were conducted by Dr. Y. D. Sharma. Samples submitted by Director General of Archaeology (DGA), New Delhi. *Comment*:  $^{14}\text{C}$  dates assign a post-Harappan period to Bara Culture.

TF-1204, Bara Culture,  $3690 \pm 150$   
(3795  $\pm$  155)

Wood charcoal from Bara 6, Pit 2 sealed by Layer 3, depth 0.8 m., Field No. Bara-6/2/1971. *Comment*: trench is on the slope of the mound.

TF-1205, Bara Culture,  $3730 \pm 95$   
(3840  $\pm$  95)

Wood charcoal from Bara 5, Layer 9, depth 2.2 m, Field No. Bara-5/3/1971.

TF-1207, Bara Culture,  $3490 \pm 85$   
(3595  $\pm$  90)

Wood charcoal from Bara 7, Pit 1 sealed by Layer 1, depth 1.2 to 1.4 m, Field No. Bara-7/5/1971.

### Barudih, Bihar, India

Barudih (Lat.  $22^{\circ} 45' \text{ N.}$ , Long.  $85^{\circ} 57' \text{ E.}$ ), District Singhbhum, is a Neolithic Culture site. Samples submitted by Dr. A. K. Ghosh, Calcutta University, Calcutta. *Comment*: Site appears to be a backwater of Neolithic Culture of Bihar.

TF-1099, Neolithic Culture,  $2625 \pm 105$   
(2700  $\pm$  110)

Carbonaceous clay from Locus N-S 0.68 m. E-W 0.45 m, depth 1.74 m, sample No. 2 (Acc. No. 141).

TF-1100, Neolithic Culture,  $2920 \pm 200$   
(3005  $\pm$  210)

Carbonaceous clay from Locus N-S 29.5 to 56 cm, E-W 12.5 to 37.5 cm, depth 91.3 cm, sample No. 3 (Acc. No. 144).

TF-1101, Neolithic Culture,  $2475 \pm 85$   
(2545  $\pm$  90)

Carbonaceous clay from Locus N-S 38 cm, E-W 59.5 cm, depth 104 to 114 cm, sample No. 4 (Acc. No. 152).

TF-1102, Neolithic Culture,  $2540 \pm 90$   
(2610  $\pm$  90)

Carbonaceous clay from Locus N-S 31.5 to 57 cm, E.W. 62.0 to 98.5 cm, depth 94.3 cm, sample No. 5 (Acc. No. 147).

### Chirand, Bihar, India

Chirand (Lat.  $25^{\circ} 45' \text{ N.}$ , Long.  $84^{\circ} 45' \text{ E.}$ ), District Saran, is a Black-and-Red Ware site. The site was excavated by Dr. B. P. Sinha, Patna University, Patna, who submitted the samples. *Comment*:  $^{14}\text{C}$  dates push the age of Neolithic-Chalcolithic period at Chirand back to c. 1700 B.C. Samples below layer 14 show mix-up, perhaps due to subsidence.

TF-1028, Black-and-Red Ware, 3390  $\pm$  90  
(3490  $\pm$  90)

Charcoal from Trench CRD-XI, Layer 10, depth 6.5 m.

TF-1029, Black-and-Red Ware, 2915  $\pm$  85  
(3000  $\pm$  90)

Charcoal from Trench CRD-XI, Layer 10, depth 6.5 m.

(3175  $\pm$  105)

Wood from Trench E7, Layer 4.

#### **Kalibangan, Rajasthan, India**

The twin mounds of Kalibangan (Lat. 29° 25' N., Long. 74° 05' E.), District Sri Ganganagar, are located on the banks of Ghaggar (now dried). Excavations were conducted under the joint supervision of Ss. B. B. Lal and B. K. Thapar. Submitted by the DGA.

TF-160, Harappa Culture, 4060  $\pm$  100  
(4180  $\pm$  105)

Charcoal from Trench XC1, Qd. 2, Layer 12, depth 3.65 m.

TF-942, Harappa Culture, 4055  $\pm$  110  
(4175  $\pm$  115)

Charcoal from Trench XA1, Qd. 4, Layer 12, depth 3.45 m. Rootlets removed.

TF-946, Harappa Culture, 3605  $\pm$  100  
(3715  $\pm$  105)

Wood charcoal from Trench ZN1, Qd. 1, Layer 7, depth 2.25 m. Rootlets removed.

TF-947, Harappa Culture, 3765  $\pm$  85  
(3875  $\pm$  90)

Wood charcoal from Trench C5, Qd. 3, Layer 34, depth 5.2 m. Rootlets removed.

TF-948, Harappa Culture, 3815  $\pm$  100  
(3930  $\pm$  100)

Charcoal from Trench C5, Qd. 3, Layer 22 depth 3.10 m, Rootlets removed.

**Kodekal, Mysore, India**

TF-748, *Neolithic Culture*, 4285  $\pm$  105  
(4410  $\pm$  105)

Charcoal from Kodekal (Lat. 16° 21' N., Long. 76° 24' E.), District Gulbarga, Trench 2, Layer 4, depth 2 to 3 m, Field No. 948. Sample submitted by Director, Deccan College, Poona.

**Palavoy, Andhra Pradesh, India.**

Palavoy (Lat. 14° 31' N., Long. 77° 09' E.), Anantpur. Sample submitted by Director, Deccan College, Poona.

TF-699, *Ashmound, Modern*

Carbonaceous ash (dung) from Layer 2. Comment: Iron slag was found with the sample.

TF-700, *Neolithic*, 3390  $\pm$  95  
(3490  $\pm$  100)

Carbonaceous ash (dung) from Layer 7, depth 3.0 m, sample No. 2.

TF-701, *Neolithic*, 3805  $\pm$  100 (3915  $\pm$  105)

Charcoal from Layer 9, depth 3.5 m, sample No. 3.

**Surkotada, Gujarat, India.**

Surkotada (Lat. 23° 37' N., Long. 70° 50' E.), District Kutch, was excavated by J. P. Joshi. It revealed a huge fortified Harappan settlement. Sample submitted by the DGA.

TF-1294, *Harappa Culture*, 3620  $\pm$  95  
(3730  $\pm$  100)

Charcoal from Trench XCI, Qd. 3, Layer 3, depth 2.4 to 2.9 m.

TF-1295, *Harappa Culture*, 3780  $\pm$  95  
(3890  $\pm$  100)

Charcoal from Trench G 1, Qd. 3, Layer 8, depth 1.9 to 2.05 m.

TF-1297, *Harappa Culture*, 3635  $\pm$  95  
(3740  $\pm$  95)

Charcoal from Trench C 1, Qd. 4, Pit 1 sealed by Layer 3, depth 2.1 m.

TF-1301, *Harappa Culture*, 3840  $\pm$  130  
(3950  $\pm$  135)

Charcoal from Trench B 1, Qd. 3, Layer 17, depth 5.65 m.

TF-1304 and 1309, *Harappa Culture*, 3645  $\pm$  90  
(3755  $\pm$  90)

Charcoal from Trench ZA 1, Qd. 2, Layer 18 A and 20, depth 6.6 to 7.15 m.

TF-1305, *Harappa Culture*, 3890  $\pm$  95  
(4005  $\pm$  100)

Charcoal from Trench ZA 1, Qd. 2, Layer 19, depth 7.25 m.

TF-1307, *Harappa Culture*, 3510  $\pm$  105  
(3610  $\pm$  110)

Charcoal from Trench XA 4, Qd. 1, Layer 5, depth 1.6 m.

TF-1311, *Harappa Culture*, 3625  $\pm$  90  
(3730  $\pm$  90)

Charcoal from Trench ZA 1, Qd. 2, Layer 4, depth 2.4 m.

## INTERNATIONAL CONFERENCE ON RAPIDLY QUENCHED METALS

Papers are solicited for the Second International Conference on "Rapidly Quenched Metals" to be held at Massachusetts Institute of Technology (MIT), Cambridge, U.S.A. from November 17 to 19, 1975. The Conference is jointly organized by MIT and Northeastern University and it is anticipated that the proceedings will be published in the form of a book.

The Conference will focus attention on the formation, structure and properties of amorphous and crystalline metastable metals produced by rapid quenching of the liquid deposition from the vapour or deposition from a solution.

A Workshop on "State-of-the-Art and Prospects for Magnetic, Electronic and Mechanical Applications of Amorphous Metals" will be held at Northeastern University, Boston, Massachusetts, U.S.A. from November 20 to 21, 1975.

Those interested in contributing papers should submit an abstract of about 300 words (in duplicate) to Prof. T. R. Anantharaman, Department of Metallurgical Engineering, Banaras Hindu University, Varanasi 221005 by June 1, 1975. The papers must be research papers and must be presented by one of the authors; substitute speakers will not be accepted.

## LETTERS TO THE EDITOR

### A NOTE ON CYLINDRICALLY SYMMETRIC SPACE-TIMES AND PETROV'S CLASSIFICATION

In the invariant theory of gravitational radiation the Riemann curvature tensor plays the central part. Petrov<sup>1</sup> gave classification of vacuum Reimann curvature tensors. Since Weyl's conformal curvature tensor possesses all symmetry properties of the Riemann tensor for non-empty gravitational fields, the algebraic classification of Weyl's conformal curvature tensor can be carried out exactly as in the case of vacuum Riemann tensor. In this paper the Weyl's conformal curvature tensor corresponding to the cylindrically symmetric space-time is classified.

The Einstein-Rosen<sup>2</sup> metric for the cylindrically symmetric space-time may be expressed in the cylindrical polar co-ordinates  $r, \phi, z$  and time  $t$  as

$$ds^2 = e^{2A-2B} (dt^2 - dz^2) - r^2 e^{-2B} d\phi^2 - e^{2B} dr^2 \quad (1)$$

where  $A$  and  $B$  are functions of  $r$  and  $t$  only.

With the help of the expressions for the Riemann curvature tensor and Ricci tensor for metric (1), the non-vanishing components of the Weyl's conformal curvature tensor are

$$\begin{aligned} C_{1212} &= -r^2 e^{-2B} C_{3434} = (m - \sigma) r^2 e^{2A-2B} \\ C_{1224} &= r^2 e^{-2B} C_{1334} = nr^2 e^{2A-2B} \\ C_{2124} &= -r^2 e^{2B} C_{1313} = (m + \sigma) r^2 e^{2A-2B} \\ C_{1114} &= -r^{-2} e^{1A-2B} C_{2223} = 2me^{1A-2B} \end{aligned} \quad (2)$$

where

$$\begin{aligned} m &= e^{2B-2A} \left[ \frac{B_{11}}{6} - \frac{B_{44}}{6} + \frac{A_{44}}{6} - \frac{A_{11}}{6} - \frac{(B_1)^2}{3} \right. \\ &\quad \left. + \frac{(B_1)^2}{3} - \frac{B_1}{3r} \right] \\ \sigma &= e^{2B-2A} \left[ \frac{B_{11}}{2} + \frac{B_{44}}{2} - A_1 B_1 - A_4 B_4 + (B_1)^2 \right. \\ &\quad \left. + (B_1)^2 + \frac{A_1}{2r} \right] \\ n &= e^{2B-2A} \left[ B_{14} + 2B_1 B_4 - A_1 B_1 - A_4 B_4 + \frac{A_1}{2r} \right] \end{aligned} \quad (3)$$

Here and in what follows, the subscripts 1 and 4 after  $A, B$  represent a partial differentiation with respect to  $r$  and  $t$  respectively.

Now following Pirani's<sup>3</sup> scheme, the physical components of the Weyl's conformal curvature tensor given in (2) with the help of the tetrad

$$\lambda_{(a)}^i = \text{diag.} \left( e^{B-A}, \frac{e^B}{r}, e^{-B}, e^{-A} \right) \quad (4)$$

can be written in the form

$$C_{AC} = \\ (A, B = 1, 2, \dots, 6)$$

$$\begin{bmatrix} -2m & 0 & 0 & 0 & 0 & 0 \\ 0 & m + \sigma & 0 & 0 & 0 & n \\ 0 & 0 & m - \sigma & 0 & n & 0 \\ 0 & 0 & 0 & 2m & 0 & 0 \\ 0 & 0 & n & 0 & m - \sigma & 0 \\ 0 & n & 0 & 0 & 0 & -m + \sigma \end{bmatrix} \quad (5)$$

If

$$C_{AB} = \begin{bmatrix} M & N \\ N & -M \end{bmatrix}$$

then

$$P = M + iN \quad \begin{bmatrix} -2m & 0 & 0 \\ 0 & m + \sigma & in \\ 0 & in & m - \sigma \end{bmatrix} \quad (6)$$

The roots of the characteristic equation

$$\begin{aligned} \lambda_1 &= -2m, \quad \lambda_2 = m + \sqrt{\sigma^2 - n^2}, \\ \lambda_3 &= m - \sqrt{\sigma^2 - n^2} \end{aligned} \quad (7)$$

In general the roots  $\lambda_1, \lambda_2, \lambda_3$  are different, and hence according to Synge<sup>4</sup> the canonical form of the Weyl's tensor is of type-I.

Now let us introduce the conditions

$$\sigma^2 - n^2 = 0 \quad \text{and} \quad m \neq 0 \quad (8)$$

Then from (3)

$$\begin{aligned} B_{11} + B_{44} - 2A_1 B_1 - 2A_4 B_4 + 2(B_1)^2 \\ + 2(B_4)^2 + A_{1/r} \\ = \pm (2B_{14} + 4B_1 B_4 - 2A_1 B_1 - 2A_4 B_4 \\ + A_{1/r}) \end{aligned} \quad (9)$$

and

$$B_{11} - B_{44} + A_{11} - A_{44} + 2(B_1)^2 - 2(B_4)^2 - 2B_{1/r} \neq 0 \quad (10)$$

The conditions (9) and (10) remain true if  $A(t \pm r)$  and  $B(t \pm r)$  and in this case the eigen vector corresponding the root  $-2m$  is non-null but the eigen vector corresponding to the repeated root  $m$  is null. Also  $Q = (P - mI) (P + 2mI) \neq 0$ , hence the Weyl's curvature tensor for this space-time is of the type-II.

Further if metric tensor satisfy the conditions

$$\sigma = \pm n \quad \text{and} \quad m = 0 \quad (11)$$

Then all three repeated roots of characteristic equation are equal to zero.

Let  $A = A(t \pm r)$ , then (11) is true if  $B = B(t)$  and

$$\frac{d^2 B}{dt^2} - 2 \left( \frac{dB}{dt} \right)^2 = 0, \text{ i.e.,}$$

$$B(t) = \frac{D}{2} \log(t - C) \quad (12)$$

where  $C$  and  $D$  are arbitrary constants.

Now

$$P = \begin{bmatrix} 0 & 0 & 0 \\ 0 & \sigma & i\sigma \\ 0 & -i\sigma & -\sigma \end{bmatrix} \neq 0, \text{ and } P^2 = 0.$$

There exists only one null eigen vector and all vectors orthogonal to it are also eigen vectors. Hence the Weyl's conformal curvature tensor for this space-time is of type-N.

The author wishes to express his indebtedness to Prof. P. C. Vaidya and Dr. J. Krishna Rao for their help in the preparation of this note.

### NORMAL COORDINATE ANALYSIS OF THE OXYPENTAFLUORIDES OF OSMIUM AND RHENIUM

THE infrared and Raman spectra of  $\text{OsOF}_5$ ,  $\text{ReOF}_5$  and  $\text{IOF}_5$  have been reported by Holloway *et al.*<sup>1</sup>. They have assigned the fundamentals on the basis of a  $C_{4v}$  symmetry. The vibrational spectra and vibrational analysis of  $\text{IOF}_5$  have been reported previously<sup>2</sup>. No such analysis, however, appears to have been carried out for  $\text{OsOF}_5$  and  $\text{ReOF}_5$ . The present work, therefore, was undertaken to extend the normal coordinate treatment to these two molecules. A general valence force field is assumed and the analysis carried out, using Wilson's F-G matrix method<sup>3</sup>.

Molecules with the same structure have been previously studied by various workers<sup>2,4,5</sup>. The set of symmetry coordinates used in the present work is the same as that used by Smith and Begun<sup>2</sup>. The fifteen normal modes of an  $\text{XYZ}_5$  type of a molecule belonging to the  $C_{4v}$  symmetry are classified as  $4a_1 + 2b_1 + 1b_2 + 4e$ , all of which are Raman active while only  $a_1$  and  $e$  are i.r., active. The Raman data reported by Holloway *et al.*<sup>1</sup>, are used in

the present calculations of the force field. The expressions for the symmetrized F and G matrix elements are the same as those reported by Smith and Begun<sup>2</sup>.

The structural parameters<sup>6</sup> used to evaluate the G matrix elements are:  $D = 1.74 \text{ \AA}$ ,  $d_5 = 1.72 \text{ \AA}$ ,  $d = 1.78 \text{ \AA}$ ,  $\angle \alpha = \angle \beta = \angle \gamma = 90^\circ$  for  $\text{OsOF}_5$  and  $D = 1.90 \text{ \AA}$ ,  $d_5 = 1.93 \text{ \AA}$ ,  $d = 1.93 \text{ \AA}$ ,  $\angle \alpha = \angle \beta = \angle \gamma = 90^\circ$  for  $\text{ReOF}_5$ . The force constants were adjusted by successive approximations and the resulting values are reported in Tables I and II

TABLE I

Force constants, and observed and calculated frequencies of  $\text{OsOF}_5$

| Force constants<br>(mdyn/\AA) | Frequencies ( $\text{cm}^{-1}$ ) |       |
|-------------------------------|----------------------------------|-------|
|                               | Obs.                             | Calc. |

| $f_{\gamma\gamma} = 0.122$    | 715                              | 717   |
| $f_{a\beta} = 0.204$          | 367                              | 355   |
|                               | 260                              | 275   |
|                               | 125                              | 119   |

along with the observed and calculated frequencies for  $\text{OsOF}_5$  and  $\text{ReOF}_5$  respectively. It can be seen that the axial M-F stretching constant ( $f_{a5}$ ), in both the cases, is greater than the equatorial M-F stretching constant ( $f_a$ ). This result is consistent with those obtained previously<sup>2-4,5</sup> and suggests stronger axial than the equatorial M-F bonding (M=Os, Re). The three stretching force constants— $f_a$ ,  $f_{a4}$  and  $f_5$ —are comparable in magnitudes with the corresponding values reported<sup>2</sup> for  $\text{IOF}_5$  which are 6.99, 4.60 and 4.42 mdyne/Å, respectively.

FIG. 1. Internal coordinates of  $\text{MOF}_5$ .

The quantitative estimate of the force field in the case of such molecules of rather unusual structure is of importance for the future vibrational studies of related systems. In fact, based on the results of  $\text{ReOF}_5$  reported here, we have completed the assignment of the vibrational spectrum of  $\text{ReOF}_4$  by a normal coordinate analysis from an incomplete assignment recently reported<sup>7</sup>.

We thank Dr. K. Sathianandan for encouragement and critical discussions. A Junior Research Fellowship by C.S.I.R. to one of the authors (V. C. D.) is also gratefully acknowledged.

## ELECTRON SPIN RESONANCE AND OPTICAL SPECTRA OF COPPER (II)-PEPTIDE-AMINO ACID MIXED-LIGAND COMPLEXES

IMPORTANCE of copper ion in biological processes has led in recent years to investigate the naturally occurring systems and model compounds<sup>1</sup>. The activity of biological macromolecules containing copper ion depends upon the selective binding of different functional groups with the metal<sup>2</sup>. For instance enzymatic reactions involving copper occur with the formation of mixed-ligand complexes<sup>3</sup>. Mixed-ligand complexes of copper with amino acids have been isolated from human serum and the complexes appear to play a role in transporting copper through biological membranes<sup>4</sup>. We have undertaken to study the properties of copper (II)-peptide-amino acid mixed-ligand complexes in a systematic way using ESR and visible spectral measurements. This communication presents the results obtained using glycylglycine, glycine and  $\beta$ -alanine as ligands. Simple complexes of these ligands with copper (II) are well studied and the spectral properties are known. Yokoi *et al.* have reported the e.s.r., spectra of several mixed-ligand complexes of copper (II) with amino acids and amines<sup>5</sup>.

### Experimental

Simple complexes were prepared according to the procedure in the literature. E.s.r. spectra were measured in a Varian E-4 X-band instrument using a  $10^{-2}$  M solution of copper – simple complexes in 1 : 1 water-methanol solution. The spectra of the mixed-ligand complexes were obtained by using a solution of 1 : 1 mixture of the two different simple complexes in 1 : 1 water-methanol.

Visible absorption spectra were scanned under identical conditions at 25° C using a SP 700 A Unicam recording spectrophotometer.

### Results and Discussion

When the copper (II) complexes  $\text{CuX}_2$  and  $\text{CuY}_2$  are mixed together the following equilibrium is established.

with the disproportionation constant given by

$$K_{\text{DXY}} = \frac{[\text{CuXY}]^2}{[\text{CuX}_2][\text{CuY}_2]}$$

From the e.s.r. spectra of the solutions, it could be seen that the line shapes were similar to those observed for single species. If more than one species were present in significant amounts the observed spectrum should have been an admixture of those for the simple complexes. In all the cases studied the line shapes of the spectra were different from the spectra of the simple complexes and the

| Cu (gly) (glygly)               | .. | 636                    | 2.226              | 2.054              | 187                                       | 0.528 |
| Cu ( $\beta$ -ala) (glygly)     | .. | 636                    | 2.215              | 2.052              | 176                                       | 0.502 |

recorded spectra were due to mixed-ligand complexes only. Results published earlier from this laboratory also show that mixed-ligand complexes in general are more stable than the simple complexes<sup>6</sup>.

E.s.r. spectra of the complexes studied show the general pattern characteristic of tetragonal copper (II) complexes with an intense absorption at high field and two or three peaks of less intensity at low fields.  $g_{\parallel}$ ,  $g_{\perp}$  and  $A_{\parallel}$  values were calculated from the low temperature spectra (77° K) and are given in Table I.  $g_{\perp}$  values should be regarded as somewhat approximate since the spectra are not well resolved. At room temperature due to rapid rotations of the molecules anisotropic couplings are averaged out leaving only the isotropic ones, observed spectrum indicates average  $g$  value only.  $g_{\parallel}$  values for the mixed-ligand complexes are found to be in between the  $g_{\parallel}$  values of the simple complexes. In the case of Cu (glygly) ( $\beta$ -ala) complexes although  $g_{\parallel}$  value of the mixed-ligand complex is nearly equal to that of Cu(glygly)<sub>2</sub>,  $A_{\parallel}$  value is in between those observed for the simple complexes. Orbital reduction factors  $a^2$  were calculated using the simplified equation.

$$g_{\parallel} = 2.0023 \left( 1 - \frac{4a^2\lambda}{\Delta} \right)$$

where  $\lambda$  is the spin-orbit coupling constant<sup>7</sup>.  $a^2$  values indicate that the bonding between copper and ligands is covalent in nature with delocalization of electron density into ligand orbitals.

From the e.s.r. data of the naturally occurring copper containing proteins, two types of molecules could be classified, one with considerably higher  $A_{\parallel}$  values than the other type<sup>8</sup>. It is believed that the site symmetry of copper ion in one case is nearly coplanar and in the other distorted tetrahedron<sup>9</sup>. Work is in progress to determine whether copper (II) ion could be forced into a tetrahedron

environment by employing high molecular weight peptides and other ligands.

#### PIPERIDINIUM AND PYRROLIDINIUM TETRATHIOMOLYBDATES AND TETRATHIOTUNGSTATES

EXTENSIVE work has been carried out<sup>1,2</sup> on alkali metal chalcogenomolybdates and chalcogenotungstates. In continuation of our investigations on thiometallates stabilized by bulky non-spherical counter cations<sup>3,4</sup> studies on piperidinium (pipH) and pyrrolidinium (pyrH) tetrathiomolybdates and

tetrathiotungstates are briefly reported in this paper. The compounds are characterized by u.v., visible and i.r. spectral measurements and thermogravimetric analysis.

Tetrathiomolbdates and tetrathiotungstates of piperidinium and pyrrolidinium were prepared by interacting molybdic oxide or tungstic oxide with about 70% aqueous piperidine or pyrrolidine taken approximately in 1:5 molar ratio. The contents were stirred at 60° with a magnetic stirrer till most of the metal oxide dissolved. The resultant solution was filtered and hydrogen sulphide was passed for 4-6 h. The crystallized tetrathiometalate was filtered, washed with a small amount of acetone and ether and air-dried. The compounds were analyzed for nitrogen, sulphur and metal contents and the analytical results are given in Table I.

The electronic spectra of the compounds taken in water on Beckman DK 2 spectrophotometer gave three characteristic absorption maxima with the molar absorptivity greater than  $10^3$  (Table II). The absorption frequencies are assigned<sup>5</sup> to  $t_1 \rightarrow 2e$  ( $\nu_1$ ),  $t_1 \rightarrow 4t_2$  ( $\nu_2$ ) and  $3t_2 \rightarrow 2e$  ( $\nu_3$ ) electronic transitions according to Viste-Grey M.O. scheme<sup>6</sup>.

Tetrathiomolbdates and tetrathiotungstates exhibit<sup>7</sup> triply degenerate infrared active bands due to M-S vibration in the region 450-500 and 160-180  $\text{cm}^{-1}$ . The present compounds examined on Beckman IR 11 spectrometer gave bands around 460 and 170  $\text{cm}^{-1}$  which are assigned to M-S stretching vibrations.

The thermal decomposition studies of the thiosalts carried out in air and nitrogen atmosphere on Netzsch thermal analyzer indicate that the compounds start decomposing around 120°. The thermal

The thiometalates are highly soluble in water and precipitate out the respective metal trisulphides on acidification. They are insoluble in ether, ethylacetate, chloroform, carbon tetrachloride, benzene, nitrobenzene, etc. The solids slowly give out hydrogen sulphide and amines with time resulting in the formation of metal trisulphides.

behaviour was found to be similar to that of ammonium tetrathiosalts<sup>8,9</sup>. Around 300° the weight-loss curves indicate the formation of metal trisulphides. The final products of decomposition obtained around 500° on chemical analysis were found to be MoO<sub>3</sub> and WO<sub>3</sub>. When heated in nitrogen atmosphere the final products obtained

around 450° were found on analysis to be metal disulphides. This agrees very well with the weight loss sustained during the decomposition.

The author is thankful to Prof. O. Glemser, Göttingen, W. Germany, for providing facilities to carry out the experimental work and to Prof. G. Aravamudan, for his interest in the work.

### ESTIMATION OF THIOSEMICARBAZIDE AND ITS METAL COMPLEXES WITH DICHLORAMINE-T

RECENTLY, dichloramine-T (N,N'-dichloro-p-toluene sulphonamide, hereinafter abbreviated to DCT) has been introduced as an oxidimetric titrant by Jacob and Nair<sup>1</sup> in non-aqueous and partially aqueous media and it has been used for oxidizing a variety of compounds<sup>2-4</sup>. Thiosemicarbazide (TSC) is an important compound which is used in the characterization of aldehydes, ketones and polysaccharides and as a metal complexing agent. Chloramine-T has been used as an analytical reagent for estimating TSC and its metal complexes<sup>5-6</sup>. In the present investigations we have examined the behaviour of DCT towards TSC and its metal complexes. It was found that these compounds undergo oxidation with DCT under specified conditions. Hence volumetric methods have been developed for their estimation.

**Materials and Methods.**—Thiosemicarbazide (E' Merck) was purified by recrystallization and an aqueous solution (~0.025 M) was prepared. DCT was prepared and purified by the method of Jacob and Nair<sup>1</sup>. An approximately decinormal solution of the oxidant in glacial acetic acid was prepared and standardized by the iodometric method<sup>1</sup>.

The complexes  $\text{Zn}(\text{TSC})_2\text{SO}_4$ ,  $\text{Zn}(\text{TSC})_2\text{Cl}_2$ ,  $\text{Zn}(\text{TSC})_2(\text{NO}_3)_2$ ,  $\text{Zn}(\text{TSC})_2(\text{ClO}_4)_2$ ,  $\text{Cd}(\text{TSC})_2\text{SO}_4$ ,  $\text{Cd}(\text{TSC})_2\text{Cl}_2$ ,  $\text{Hg}(\text{TSC})_2\text{Cl}_2$ ,  $\text{Ni}(\text{TSC})_2(\text{NO}_3)_2$

and  $\text{Ni}(\text{TSC})_2\text{SO}_4 \cdot 3\text{H}_2\text{O}$  were prepared by methods reported elsewhere<sup>7</sup>.

Detailed investigations of TSC system has brought out the following facts:

(I) TSC forms a complex with DCT which rapidly decomposes with a quick change of colour from orange red to pale yellow and evolution of gaseous products<sup>5</sup>. The complex has a broad absorption band around 350 mμ.

(II) Rate of oxidation is very slow with solutions of TSC in glacial acetic acid, the required stoichiometry being obtained after 16 hours.

(III) During oxidation, water content of the reaction mixture had to be maintained around 12–15% for the 1:3 stoichiometry to hold good. Slight over oxidations beyond the 12 electron change per mole of TSC were noticed when the water content is less than 12%. This can probably be attributed to the oxidation of  $\text{NH}_4^+$  ion<sup>8</sup>.

(IV) A direct titration with a visual or potentiometric end-point was not practicable.

(V)  $\text{N}_2\text{H}_4$ , KCNS and  $\text{PO}_4^{3-}$  ion interfere in the estimation.

(VI) The 1:3 stoichiometry holds only when TSC solutions are added to DCT and not *vice versa*.

**Recommended Procedure.**—Aliquots of aqueous TSC solution or of the metal complex in pH 4 buffer are added to a measured excess (~50–60%) of 0.1 N DCT maintaining the water content around 12–15% in the reaction mixture. Set aside for 30 minutes (10 minutes in the case of a metal complex), shaking occasionally. Add 10 ml of 20% KI and titrate against 0.1 N sodium thiosulphate. Run a blank with DCT solution alone. The stoichiometry of oxidation of TSC and its metal complexes can be represented by equations (1) and (2) respectively:

Where

and

Some typical results of analyses are shown in Table I and it is noticed that the results of analysis are quantitative within the limits of experimental error.

The percentage error in the estimation of TSC (2–10 mg) was about 0.5. The error was almost negligible (<0.2%) when larger quantities (12–40 mg) of TSC were taken for the estimation.

TABLE I

Estimation of thiosemicarbazide and its metal complexes with Dichloramine-T (% error for values obtained in the neighbourhood of the values indicated in the first column is given)

#### GRAVIMETRIC ESTIMATION OF BERYLLIUM AS BENZIDINE FLUORBERYLLATE

THE usual method of beryllium determination is gravimetric<sup>1</sup> as oxide which, though accurate, is not free from interferences, particularly in presence of aluminium. In the present method beryllium can be estimated in the presence of other ions without much of separation procedure.

In the present method beryllium was precipitated as benzidine fluoroberyllate. Beryllium in solution is first converted into fluoroberyllate by the addition of fluoride ion in excess and then precipitated with benzidine in acetic acid solution. Beryllium in rocks and minerals can easily be converted into fluoroberyllate by fusion with alkali bifluoride and then precipitated as benzidine fluoroberyllate. Benzidine fluoroberyllate<sup>2</sup> like benzidine sulphate is highly soluble in water, flocculent and can easily be filtered using a sintered crucible.

**Procedure.**—Beryllium chloride solution containing 10 mg to 75 mg of beryllium was taken in a 250 ml polythene beaker and diluted to 50 ml. The pH of the solution was adjusted to 3–4 with dil. hydrochloric acid. Sodium fluoride solution was now added taking care to see that the pH of the solution remained at 3–4. The solution was warmed (50°–60° C) and an excess of benzidine (2%) solution in 2 N acetic acid was added along the side of the beaker with constant stirring. It was cooled and filtered through a sintered glass crucible (No. 4), washed with 0.1 M acetic acid, dried in an air oven at 110° C and weighed as benzidine fluoroberyllate. Ten determinations were carried out with varying quantities (20–70 mg) of Be and the mean average error was 0.3%.

**Procedure for Rock and Minerals.**—0.25 gm. of the sample was taken in a platinum crucible and fused with 3–4 times its weight of potassium bifluoride. The fused mass was taken up with water and transferred to a beaker and boiled. If there is a precipitate it should be filtered off. The pH of the solu-

tion was adjusted to 3-4 and then proceeded as stated in the general method.

### CHARGE-TRANSFER COMPLEX: INTERACTION OF PENTAATOMIC IODINE CATION WITH DIMETHYLSULFOXIDE

EVER since Mulliken<sup>1</sup> published his work on the electron donor-acceptor systems, a great deal of work has appeared in the literature on the interaction of iodine with electron donors. In this note, we are reporting for the first time, the interaction of iodine pentaatomic cation, which is a more stable species compared to the other iodine poly-cations<sup>2-6</sup>, with the electron donor, dimethylsulfoxide, DMSO, in sulphuric acid.

Since iodine and sulphuric acid are both Lewis acids, no electron exchange should occur when they are mixed. The appearance of iodine band at 503 nm<sup>7</sup>, in 98.1% H<sub>2</sub>SO<sub>4</sub> (Iodine absorbs at 520 nm in *n*-heptane) shows that there is a slight interaction between iodine and sulphuric acid. No other bands could be detected within six hours. The iodine absorption band shows a blue shift in the visible region, as the concentration of sulphuric acid is decreased from 98% to ~20%; below 20%, new bands appear at 290 and 355 nm which are due to I<sub>3</sub><sup>-</sup>.

If the low wavelength absorption of iodine in H<sub>2</sub>SO<sub>4</sub> is due to solute-solvent interaction, the addition of a base solvent, such as water, should affect the absorption and it is indeed observed in the case of water-iodine-sulphuric acid system. At present we are not in a position to suggest any model for such an interaction.

Solutions of iodine in sulphuric acid (> 85% by weight) on standing develop an absorption at 330 nm; we could not detect any band or shoulder around 280 nm in our open cell system<sup>2</sup> (Cary-14R Spectrophotometer). The band at 330 nm is ascribed to the I<sub>5</sub><sup>+</sup> ion which formed by the slow reaction<sup>3</sup>,

When DMSO, an electron donor, is added to a solution containing I<sub>5</sub><sup>+</sup>, the intensity of I<sub>5</sub><sup>+</sup> band (330 nm band) is slightly enhanced and a new band appears at ~350 nm (Fig. 1). The intensity of this new band depends upon the concentration of the DMSO. This behaviour is the typical charac-

teristic of molecular complexes<sup>8,9</sup>. So, the new band can be ascribed as the charge-transfer band which arises due to the interaction of DMSO with I<sub>5</sub><sup>+</sup> in sulphuric acid. The low CT energy of DMSO-I<sub>5</sub><sup>+</sup> (3.54 eV) as compared to that of DMSO-I<sub>2</sub> (4.23-4.58 eV)<sup>10</sup> shows clearly that I<sub>5</sub><sup>+</sup> is a better electron acceptor than iodine molecule itself<sup>8</sup>.

Fig. 1. Absorption spectra of iodine and DMSO in H<sub>2</sub>SO<sub>4</sub>: (1) Iodine in H<sub>2</sub>SO<sub>4</sub> after 72 hours; (2) iodine solution of the same concentration as that of (1) and DMSO; (3) the difference between curves 1 and 3.

The author is thankful to CSIR (India) for financial support, to Prof. G. B. Singh, Head, Department of Chemistry, for providing the research facilities and to Mr. Bipin for helping in recording the spectra.

# AMINO ACID COMPOSITION OF EYE LENS OF THE FISH *LABEO BATA* AT DIFFERENT STAGES OF GROWTH

BESIDES the study of the amino acid composition of eye lens of frog, bovine<sup>1</sup> and human being<sup>2</sup>, the changes in protein constituents of eye lens, with the changes in growth, have been studied in rat<sup>3</sup> and human beings<sup>4,5</sup>. No attention has been paid to the study of protein constituent of eye lens in a fish. Therefore to fill the lacuna, the present study is devoted to investigation of the changes in amino acid composition of eye lens of *Labeo bata* at three different stages of growth.

A collection of *Labeo bata* was made from Keetham Lake (Near Agra) and they were grouped according to their length. By dissecting the eyes, the eye lenses of fishes were taken out. Lenses were washed thoroughly with several changes of distilled water, dried in an oven at 100° C and finally ground to fine powder. Total nitrogen in the powder of each group was determined by semi-micro Kjeldhal's method.

Three test samples each equal to about 200 mg of crude protein were hydrolysed with 6 N-HCl under reflux for 24 hours. The hydrolysate was taken in warm water and then filtered. The filtrate was decolorised with a little Darco G-60. After removal of carbon the hydrolysate was evaporated to dryness under reduced pressure and finally dissolved in 10% vol/vol 2-propanol and made up to a definite volume. Tryptophan of the test sample was determined separately by hydrolysis with 10% wt/vol Ba(OH)<sub>2</sub> under reflux for 20 hours.

Complete separation and identification of amino acids were achieved by applying two-dimensional paper chromatography using phenol-water (4:1 wt/wt) as one set and *n*-butanol-acetic acid-water (60:15:25 vol/vol) as another set of solvents.

For estimating individual amino acids chromatograms of a known mixture of amino acids and unknown hydrolysate samples were developed by spraying 0.2% ninhydrin in 2-4% acetic acid in acetone and drying the paper at 60° C for 15 min. Individual coloured spots were cut out from the chromatograms and eluted in 0.42% NaHCO<sub>3</sub> in 48% ethanol and kept undisturbed overnight. The colour intensity of known and unknown samples was read in spectrophotometer.

With the readings of known and unknown samples amino acids in g/100 g of dry eye lens were calculated.

The length and average weight of fish of each group is given in Table I.

Amino acids and total nitrogen of eye lens of fish *Labeo bata* are given in Table II.

TABLE I

|             | Stage I | Stage II | Stage III |
|-------------|---------|----------|-----------|
| Length (cm) | 8       | 20       | 25        |
| Weight (gm) | 30      | 250      | 350       |

TABLE II

*Amino acids of eye lens at different stages of growth of fish Labeo bata*

(Values are expressed in gm/100 gm of dry matter)

| Amino acid     | Stage I | Stage II | Stage III |
|----------------|---------|----------|-----------|
| Alanine        | 3.9     | 3.8      | 3.8       |
| Arginine       | 8.5     | 8.6      | 8.7       |
| Aspartic acid  | 2.4     | 2.3      | 2.3       |
| Cystine        | 1.9     | 2.0      | 2.1       |
| Glutamic acid  | 4.1     | 4.1      | 4.0       |
| Glycine        | 3.7     | 3.7      | 3.7       |
| Histidine      | 2.1     | 2.2      | 2.2       |
| Hydroxyproline | 1.2     | 1.3      | 1.3       |
| Isoleucine     | 1.4     | 1.3      | 1.3       |
| Leucine        | 1.6     | 1.6      | 1.7       |
| Lysine         | 2.3     | 2.3      | 2.4       |
| Methionine     | 1.6     | 1.7      | 1.7       |
| Phenylalanine  | 1.6     | 1.5      | 1.5       |
| Proline        | 2.7     | 2.8      | 2.9       |
| Serine         | 3.5     | 3.5      | 3.6       |
| Threonine      | 2.5     | 2.5      | 2.5       |
| Tryptophan     | 1.3     | 1.4      | 1.4       |
| Tyrosine       | 4.1     | 4.2      | 4.2       |
| Valine         | 2.6     | 2.5      | 2.5       |
| Total nitrogen | 14.4    | 14.5     | 14.5      |

Table II clearly indicates that each of the growth stages contains 19 amino acids of lens proteins. Changes in amino acid contents from one to the other stages are not appreciable. Similarly total nitrogen content too does not change significantly from one stage to the other. At all the three stages of growth, arginine is present in maximum quantities of all the amino acids. At the stage I glutamic acid and tyrosine are present in equal quantities. At the stage II aspartic acid and lysine occur in equal amounts. A comparison with bovine eye lens<sup>2</sup> shows that total nitrogen content of the fish eye lens is lower than that of bovine lens. Bovine eye lens<sup>2</sup> contains only 14 amino acids serine, glycine, alanine, proline and hydroxy proline being absent. Bovine eye lens contains aspartic acid in maximum amount, while arginine content of the fish eye lens is maximum of all the amino acids. In the case of bovine lens arginine content is higher than the aspartic acid. Bovine eye lens contains tryptophan and methionine in equal amounts,

### IDENTIFICATION OF PYRIDOXINE HYDRO-CHLORIDE FROM MULTIVITAMIN PREPARATIONS

VARIOUS methods<sup>1,2</sup> are described in the literature for the identification of pyridoxine from multivitamin preparations, but none of them is specific. While the method of Hochberg and co-workers is only applicable when pyridoxine is in pure form<sup>3</sup>, method described in various pharmacopoeia using 2,6-dichloroquinone chloroimide is rather a negative test, based upon no colour formation in presence of boric acid. Interference of excipients such as antioxidants,  $\alpha$ -tocopherol and certain preservatives added in multivitamin preparations which give blue colouration in presence of boric acid, limits its application. Colour test described by Feigl<sup>4</sup> using 1,2-naphthaquinone-4-sulfonate, though sensitive, is not specific, as this reagent reacts with all compounds containing two removable hydrogen atoms attached to  $-C$  or  $-N$  atom.

In this paper a new reagent for the identification of pyridoxine in multivitamin preparations by thin layer chromatography is described. 2-Thiobarbituric acid reacts with  $\alpha$ , $\beta$ , unsaturated and aromatic aldehydes<sup>5</sup> giving a pink coloured compound. It is observed that primary alcoholic groups at positions 3 and 4 of pyridoxine can be converted to the corresponding aldehydes by oxidation. The aldehyde when further treated with 2-TBA reagent produces pink coloured complex. No other vitamin of the multivitamin preparation such as vitamin A, thiamine, riboflavin, ascorbic acid, pantothenic acid behaves in a similar way. Vitamin A if present in alcoholic form may interfere but the colour appears after 24 hours on TLC whereas that of pyridoxine appears within 5–10 minutes. However, since vitamin A is only fat soluble it will not interfere with vitamin B<sub>6</sub> where aqueous extract is used. Pyridoxine can also be converted to its aldehyde form using Reimer-Tiemann reaction<sup>6</sup>. The aldehyde is further treated with 2-TBA reagent as described in test-(2).

### EXPERIMENTAL

#### Reagents :

I. Methanol, Acetone and Chloroform—BDH AnalaR.

II. Dichromate in sulphuric acid : 3 g potassium dichromate (AnalaR Grade) dissolved in 100 ml of 30% sulphuric acid.

III. 2-TBA reagent for test (1)—Dissolved 2.88 gm 2-thio-barbituric acid in 100 ml aqueous solution of 0.2 M anhydrous sodium carbonate.

IV. 2-TBA Reagent for test (2)—Dissolved 10 gm 2-TBA in 90 ml perchloric acid and added 10 ml glacial acetic acid.

#### METHOD

*Test (1): Identification on TLC.*—An aqueous extract of the multivitamin tablet was spotted on a 250  $\mu$  layer of silica gel G, activated for half an hour at 110° C. Chromatogram was developed using Methanol : Acetone (7.5 : 2.5) as solvent system. The plate, after drying at room temperature, was first sprayed with potassium dichromate in sulphuric acid which oxidises  $-CH_2OH$  group to  $-CHO$  group giving a green spot. After five minutes the plate was sprayed with 2-thio-barbituric acid reagent. Pink spot appeared after heating the plate for five minutes at 110° C ( $R_f = 0.51$ ). The sensitivity is  $\sim 10 \mu$ g.

*Test (2): Detection of Pyridoxine by spot test.*—To 1.00 ml of pyridoxine solution add 1.0 ml methanolic NaOH (20%) and 1.0 ml chloroform. Keep it in boiling water-bath for five minutes. Allow it to cool to room temperature. Add 3.0 ml of acidic 2-TBA reagent and keep in boiling water-bath for 15 minutes. A pink colour develops. This reagent may be applied for the colorimetric determination of vitamin B<sub>6</sub> in multivitamin preparations (absorption maxima 537.0  $m\mu$ ). The sensitivity of this reagent is  $\sim 100 \mu$ g.

We thank Dr. B. N. Mattoo, Director, for keen interest and valuable suggestions in this work.

# STUDIES ON SOME PAPILIONACEOUS SEED OILS

WOLFF AND KWOLEK<sup>1</sup> have pointed out the necessity for collecting more information regarding legume lipids before chemotaxonomic relationships are advanced. Though the genus *Crotalaria* is a large one, consisting of about 300 species, only a few species have been investigated so far, for their lipids. We report here the physical and chemical analysis of three species of *Crotalaria*, namely, *C. juncea* Linn., *C. linifolia* Linn., *C. wightania* along with *Trigonella foenum-graecum* Linn. and *Tephrosia purpurea* Linn. (Pers.).

unsaponifiable matter, by the alkali isomerization method of Hilditch, Morton and Riley<sup>2</sup> using Beckmann DU-2 spectrophotometer. The identification of the fatty acids was carried out by subjecting total fatty acids to reverse phase paper and thin-layer chromatography, impregnating the paper and the plate (Silica gel G) with 10% liquid paraffin in benzene. Acetic acid samples 96% and 90% were used as a solvent systems for TLC and paper chromatography respectively. Iodine vapour was used as the visualising agent and authentic fatty acids were taken as reference for the identification of individual fatty acid.

TABLE I  
Characteristics of the oil

|                          | % of oil | Colour          | Sp. gr. | R <sub>f</sub> index at 25° C | Acid value | Sap. value | Ester. value | Iodine value | % unsap matte |

| <i>C. wightania</i>      | .. | 48.1                    | 3.8              | 20.4         | 27.7                           |
| <i>T. foenum graecum</i> | .. | 44.9                    | 7.9              | 28.6         | 18.6                           |
| <i>T. purpurea</i>       | .. | 30.8                    | 2.4              | 43.6         | 23.2                           |

Oil content was determined by extraction of 500 gm of powdered seeds in a Soxhlet apparatus for 36 hours with pet. ether (40-60°). Iodine value, saponification value, acid value, unsaponifiable matter, ester value, specific gravity and refractive index were determined by I. P. methods<sup>2</sup>. Linolenic acid and linoleic acid contents were determined spectrophotometrically on mixed fatty acids, free from

The percentage of oil in the six *Crotalaria* species investigated by Kapur *et al.*<sup>4</sup> ranges from 2 to 5.3% while in the species investigated it is much higher. These higher values would push the average value of the oil content in *Crotalaria* species as indicated by Earl and Jones<sup>5</sup> from 3.3%. However, this higher value would still be within the range of the tribe Genisteae which is about 12%. A comparison

of values of oleic acid in the species investigated with those reported by Kapur *et al.*<sup>4</sup> shows a close relationship of *C. linifolia* with *C. agitiflora*, *C. wightiana* with *C. sericea* and *C. juncea* with *C. rubiginosa*. However, it may be noted that the percentage of this acid in *C. mucronata* as reported is only 7.5% which does not seem to fit into the general pattern of the major fatty acid component of leguminosae in general and *Crotalaria* in particular.

Wolff and Kwolek<sup>1</sup> and Gupta and Chakrabarti<sup>6</sup> observed that the compositional difference of fatty acids reflect heridity relationship; however, it may be pointed that it also shows a phylogenetic relationship at the levels of genus and species.

## STUDIES ON OVALBUMIN AS A DILUENT IN VIROLOGICAL AND SEROLOGICAL TESTS

THE use of bovine albumin in buffered saline as a viral diluent and virus stabilizer in the field of arbovirology has been recommended by various workers<sup>1,2</sup>. The high cost and non-availability of good quality bovine albumin have compelled us to investigate the possibilities of finding a substitute. In the present studies we have used ovalbumin in virological and serological tests and the results are compared with those obtained with bovine albumin (fraction V from bovine plasma, Armour Pharmaceutical Company Limited, England).

Ovalbumin was prepared from white leghorn eggs obtained from Shreekant Poultry Farm, Narayanagaon, Poona, by sodium sulfate extraction method<sup>3</sup>. The purified albumin solution was dialysed against distilled water to remove excess of sodium sulfate. The total proteins were estimated

by the biuret method<sup>4</sup>. Appropriate quantities of albumin solution were then added to phosphate buffered saline and borate buffered saline so as to make 1.5% ovalbumin in phosphate saline (OAPS), pH 7.2 and 0.8% ovalbumin in borate saline (OABS), pH 9.0 respectively.

*Virological Tests.*—The following arboviruses were employed in the study: TR 1751 strain of Dengue type 2, Kaisodi (VRC No. G 14132), African strain of Chikungunya (CHIK), Indian strain of West Nile (VRC No. G 22886), Japanese B Encephalitis (VRC No. P 20778), and Kyasanur Forest Disease (VRC No. P. 9605). Three virus diluents were tested, viz., OAPS, BAPS (0.75% bovine albumin in phosphate buffered saline, pH 7.2) and 1:1 mixture of OAPS and BAPS. All the diluents contained 1000 units/ml of penicillin and 2 mg/ml of streptomycin.

Approximately 5 dex LD<sub>50</sub><sup>5,6</sup> of virus was incubated in each diluent for one hour at 37°C. Further ten-fold virus dilutions were made in the respective diluents. Three weeks old Swiss mice, maintained at VRC, were inoculated by intracerebral (IC) route. Each ten-fold dilution was inoculated into a group of six mice, inoculum being 0.03 ml for each mouse.

1.5% OAPS gave somewhat lower titres, maximum difference being 2.5 dex for P 20778 and minimum being 0.2 dex for P 9605, when compared to those obtained with standard diluent, BAPS. However, 1:1 mixture of OAPS and BAPS was found to be a satisfactory diluent as LD<sub>50</sub> titres for all the viruses tested were almost similar to those obtained with BAPS. When OAPS was employed in 2% concentration the difference in the titres compared to BAPS was considerably reduced.

*Serological tests.*—Haemagglutination (HA) and haemagglutination inhibition (HI) tests were performed according to the methods of Clark and Casals<sup>7</sup>. The following arbovirus antigens were employed in the study: Indian strain of Chikungunya (VRC No. 634029), Sindbis (AR 339), Dengue-1 (Hawaii, DEN-1), Dengue-2 (VRC No. P 23085), Dengue-3 (VRC No. 633798), P 20778, G 22886 and P 9605.

All the antigens were diluted 1:10 in OABS and kept overnight before testing. Another set of antigens was diluted 1:10 in standard diluent—0.4% bovine albumin in borate saline (BABS), pH 9.0 and was also kept overnight before use.

At the optimum pH values, antigens diluted in both the diluents produced similar HA titres. Comparatively higher HA titres were obtained with OABS at higher pH values for P 20778, G 22886, P 23085, and P 9605 antigens. The slight variations

in HA titres obtained at the optimum pH values in the case of AR 339 and P 23085 antigens were within the range of experimental error and thus were not significant.

Homologous mouse hyper-immune sera and fifteen previously tested survey sera (containing 5 human, 5 monkey, 2 bullock, 1 camel and 2 bird) were employed in HI test against all eight antigens to determine the specificity of haemagglutination test with OABS. The tests were performed at optimum pH values of respective antigens for both the diluents. In addition to this, HI test was also performed using OABS at wider pH ranges where comparatively higher HA titres were obtained, e.g., pH 7.0 for P 20778, G 22886 and P 9605, pH 6.0 for DEN-1, P 23085, and 633798. But at these pH values antigens did not remain stable and their titres dropped down. Comparable results were obtained at optimum pH values for both the diluents, viz., OABS and BABS.

Similar results were obtained with different batches of ovalbumin. Ovalbumin being extremely susceptible to denaturation should be stored at 4-8°C and heating, stirring and frothing should be minimised. The precipitate obtained in our stock solution of OABS and OAPS was filtered through filter paper just before use. This, however, did not affect the results.

Our studies indicate that ovalbumin alone can be used for serological tests but needs supplementation with bovine albumin for virological studies.

The authors gratefully acknowledge excellent technical assistance of Shri A. S. Malunekar and Shri V. L. Ayachit.

# AN ABNORMAL SPECIMEN OF *THYSSA* *MALABARICUS* (BLOCH) (PISCES: ENGRAULIDAE) WITHOUT PELVIC FINS

While examining the Clupeoid fishes from Madras Coast, the author came across a specimen of *Thyssa malabaricus* (Bloch) without pelvic fins (Fig. 1). This is a rare case in Engraulids and hence is being reported here.

FIG. 1. *Thyssa malabaricus* without pelvic fins.

The meristic counts and the body measurements (in mm) of the specimen are as follows:

P. 13, D. I ii 12, A. ii 38, Scutes (total) 22, G.R. 14 + 17. Total length 139.0, standard length 115.0. Head length 27.3, Body depth 39.2, Eye diameter 7.5, Snout 5.7, Prepectoral distance 29.3, Pectoral fin length 22.5, Preanal distance 70.0, Anal fin base length 37.8, Predorsal distance 55.3, Dorsal fin base length 12.0.

It can be seen that the morphometric characters in general and meristic counts in particular are agreeing with the previous descriptions of this species (Dutt<sup>1</sup>, Whitehead<sup>2</sup>) except for the number of scutes, which is somewhat less in this specimen, perhaps associated with the absence of pelvic fins.

The author is thankful to Dr. K. V. Rama Rao and the Officer-in-Charge, Marine Biological Station of Zoological Survey of India, Madras, for the Clupeoid Collections and to Dr. B. K. Tikader, Deputy Director, Western Regional Station, Zoological Survey of India, Poona, for facilities.

# STIMULATION IN SEED GERMINATION OF FODDER CROPS THROUGH GROWTH RETARDANTS

THE growth retardants, chlormequat (2-chloroethyl trimethyl-ammonium chloride), B-nine (N-dimethyl-amino succinamic acid), and Phosfon (2, 4-dichlorobenzyl tributyl phosphonium chloride) have been extensively used to study their effect on growth, development and metabolism of plants. In general they produce effects which are reversed from those produced by GA<sup>1-3</sup>. There is no report on the seed germination of fodder crops treated with these substances. Hence, the present study was aimed at finding out the response of these growth retardants on seed germination of fodder crops.

Seeds of cowpea (*Vigna unguiculata* L.) berseem (*Trifolium alexandrinum*), Vetch (*Vicia sativa* L.) and M. P. Chari (*Sorghum bicolor* L.) were separately soaked for 1 hr, 4 hr and 8 hr in 10, 100 and 1000 ppm solutions of these three retardants. For the controls, the seeds were soaked in distilled water for these durations. Seeds were placed between pairs of filter papers put on thick cotton pad in petridishes and left at room temperature ( $25 \pm 5^\circ \text{C}$ ) in the laboratory for germination. Moisture was maintained by adding known quantities of water. Three replications (100 seeds in each replication) were taken in each of the treated combinations. The number of seeds germinated on the 10th day (maximum germination) were

TABLE I

| Interaction C.D. at 5%    |      | 2.60   | 2.49    | 3.08  | 2.46        |

recorded and presented as average per cent seed germination. The critical difference values presented are, however, for the averages of the transformed variables.

The analysis of variance of the transformed data showed that the effects due to the chemicals, concentrations and the soaking durations were significant alongwith the interaction between the chemical concentration and soaking duration (Table I).

Application of the chemicals increased the seed germination percentage in all the crops except for Phosfon application to M. P. Chari. Among the chemicals, Chlormequat and B-nine were better as promoters of seed germination than Phosfon. Generally, the seed germination increased with the increase in the dosage of the chemical from 10 ppm to 100 ppm and was reduced at higher concentration. In cowpea, the increase in the concentration of phosfon, however, resulted in reduced per cent seed germination. In the control, longer soaking duration increased the germination of cowpea and vetch, whereas in berseem and M. P. Chari, the 8 hr soaking resulted in lower per cent germination than even under 1 hr soaking. Increasing the duration of soaking in the chemicals from 1 to 4 hr and 4 to 8 hr resulted in decreased seed germination of cowpea, vetch and M. P. Chari. However, the germination percentage of berseem increased with the increased duration upto 4 hr but in 8 hr soaking, it suddenly decreased and was even lower than that of 1 hr soaking period. In the present study, all the substances employed are surface active substances. They wet the seeds more effectively than plain water and hence better germination in a shorter intervals. The differences in the germination percentage among various seeds may be due to different types of porosity of the membrane covering the seeds. In general, these growth retardants promoted the germination percentage at lower concentrations and inhibited the same at higher concentration (1000 ppm). This stimulation could be attributed to the reduction in the content of inhibitors responsible for delaying or improvement in the permeability of hard seed coat facilitating growth and development of embryos. Plant growth retardants may not act exclusively as growth inhibitors but may also, under certain conditions, stimulate<sup>1-6</sup>. No explanation is offered for these extraordinary results where the effect of a growth retardant shows parallels that of gibberellin.

The results have clearly brought out that the seeds of Cowpea and M. P. Chari soaked in 100 ppm of chlormequat for 1 hr would give the maximum germination of 93.2% and 84.4% respectively. Berseem seeds soaked for 4 hr in 100 ppm of

B-nine gave maximum germination (95.3%) followed by 4 hr. soaking period in 100 ppm phosfon 95.4%. Seeds of vetch also gave maximum germination of 96.0% when soaked for 1 hr in 100 ppm of B-nine.

Thanks are due to the late Dr. M. L. Magoon, Director, for facilities and to Dr. K. L. Mehra, Head of Division, Plant Improvement, I.G.F.R.I., Jhansi, for critically going through the manuscript.

#### ROLE OF TANNIN INHIBITORS ON THE INFECTIVITY OF THREE DIFFERENT ISOLATES OF TOBACCO MOSAIC VIRUS

TANNINS are of particular interest and importance in the transmission of plant viruses because of their wide occurrence in different host plants and their virus inhibitory properties<sup>1,2</sup>.

It has been reported that only the purified preparations of the samples from coconut root wilt disease, attributed to a strain of tobacco mosaic virus<sup>3</sup>, is infectious in the form of local lesions on *Chenopodium amaranticolor* Coste and Reyn. while the crude sap is not. Coconut plants are widely known to contain tannin<sup>4,5</sup>. Tannins are known as virus inhibitors<sup>1,2</sup> and possibly playing its inhibitory role as is evident that only the purified preparations from coconut root wilt diseased samples are infectious and not the crude preparations. In view of the above, in the present experiments chemicals which are known to be tannin inhibitors were used to study the effect of these chemicals on the inhibitory influence of the tannin present in coconut host plants, thereby rendering an easy way of isolating the virus from the coconut root wilt affected palms. Numerous methods have been devised from time to time to avoid the inhibitory effects of tannin in transmitting a virus. Infectivity of tannic acid—tobacco mosaic virus (TMV) mixture was restored by adding gelatin<sup>6</sup>. Some alkaloids and soluble and insoluble proteins have also been reported to increase virus infectivity by precipitating tannin<sup>7-11</sup>.

TABLE I

Effect of different concentrations of three chemicals on the infectivity of three isolates of TMV in presence of coconut leaf sap

| Isolate of TMV    | Percentage concentration |      |      |      |           |      |      |      |             |      |      |      |
|-------------------|--------------------------|------|------|------|-----------|------|------|------|-------------|------|------|------|
|                   | Lead acetate             |      |      |      | Polyclear |      |      |      | Hide powder |      |      |      |

| Coconut root wilt | 10.1                     | 10.8 | 30.0 | 50.0 | 10.2      | 10.8 | 20.1 | 30.0 | 10.2        | 10.8 | 20.0 | 20.4 |
| Dahlia            | 10.6                     | 20.0 | 20.9 | 60.0 | 10.2      | 10.1 | 20.8 | 30.4 | 10.4        | 30.0 | 40.2 | 60.8 |

Percentage increase in infectivity over control.

Three samples of tobacco leaves infected by three different isolates of TMV, viz., chilli puri orange<sup>1,2</sup>, coconut root wilt<sup>3</sup> and dahlia<sup>1,3</sup> were macerated, the sap extracted and mixed individually with sap obtained from healthy coconut leaves since coconut plants are known to contain tannins<sup>4</sup> (1:1), and supplemented respectively by hide powder, polyclear and lead acetate to ascertain the capacity of these substances to protect the virus from precipitation by coconut leaf tannins. Standard extracts were prepared. All the samples were then centrifuged, the clear supernatants were diluted to 1:100. Four concentrations for the chemicals mentioned above were used. Polyclear and lead acetate showed negligible differences over control at concentrations below 5%; therefore, higher concentrations were tried. On the other hand, hide powder was quite effective even at lower concentrations; therefore more than 5% were not used. Identical treatment was applied to controls, consisting of a mixture of infected tobacco leaves and healthy coconut leaves in 1:1 ratio. *Chenopodium amaranticolor* plants were used for bioassay.

It is evident from Table I that all the chemicals used were found effective and conferred adequate protection on the virus isolates under study from precipitation by the coconut leaf tannins.

The authors are thankful to Dr. S. P. Raychaudhuri, for facilities and encouragement.

#### NUCLEAR POLYHEDROSIS OF *SPODOPTERA LITURA* (FABRICIUS): DESCRIPTION OF INCLUSION BODIES AND VIRIONS

A NUCLEAR polyhedrosis virus disease was recorded in the larvae of tobacco Caterpillar, *Prodenia litura* F.<sup>1</sup> in India. The species, *eridania*, *litura*, *orthogalii* and *praeifica* belonging to the genus *Prodenia* have been listed to have nuclear polyhedrosis virus disease<sup>2</sup>. In the case of *Prodenia litura*, the first record of nuclear polyhedrosis virus disease is by S. Abul-Nasr<sup>3</sup>. Bergold and Flaschentrager<sup>4</sup> described this virus as *Borrelina litura*. Later Harpaz *et al.*<sup>5</sup> observed that this insect was erroneously referred to as *Prodenia litura* (Fabr.) and referred this species as *Spodoptera littoralis* (Boisduval). C. Boursin<sup>6</sup> while reconstructing the genus *Spodoptera*, renamed *Prodenia litura* as *Spodoptera litura* (F.). The literature on nuclear polyhedrosis virus from 1956–69 contains the reference of *P. litura* though, the species dealt by various workers was *S. littoralis*.

- Allard, H. A., *J. Agric. Res.*, 1918, 13, 619.
- Stanley, W. M., *Phytopathology*, 1935, 25, 899.
- Summanwar, Arvind, S., Raychaudhuri, S. P., Jagadish Chandra, K., Nam Prakash and Lal, S. B., *Curr. Sci.*, 1969, 38, 208.

Hence, it is necessary to publish the virus under investigation in India as a new record of nuclear polyhedrosis virus in *S. litura*.

6. Boursin, C., *Ann. Natur. Mus. Wien.*, 1963, 67, 651.

Figs. 1-3

The double shadow casted polyhedra (Fig. 1) revealed an irregular form, majority of them appear hexagonal in outline. A few of them were octagonal and tetragonal. The edges of the polyhedra are rounded. The mean diameter of inclusion bodies is  $1.7 \pm 0.29 \mu$  with a range extending from 0.9 to  $2.2 \mu$ .

The partially alkali N.  $\text{Na}_2\text{CO}_3$  dissolved polyhedron stained with 2% phosphotungstic acid (Fig. 2) showed crystallisation pattern which is under investigation. The bundles containing virions are distributed randomly in the protein lattice of the polyhedron. The nuclear polyhedrosis virus of *S. litura* belongs to MNPV group, viz., many nucleocapsids per envelope.

The virions or nucleocapsids appear to be rigid rods. The average length was  $384.8 \pm 41.3 \text{ nm}$  (Fig. 3), and individual virion length ranged from 327.4 to 462.3 nm. The breadth of the virus averaged  $53.6 \pm 5.8 \text{ nm}$  with a range of 42.3 to 66.0 nm.

Philips EM 100 was used for the studies.

#### PERSISTENCE OF MALATHION RESIDUES IN PADDY PLANTS (*ORYZA SATIVA*)

RESIDUES of malathion on various crops have been determined by many workers. Hopkins *et al.* (1957) on lettuce; Wallis *et al.* (1957) on vegetable berry and tobacco crops; Waites and Van (1958) on turnip, tops, collards, snapbeans and lettuce; Pritam Singh and Rattan Lal (1966) on tomato and pea; Kavadia *et al.* (1968) on Indian rape seed; Hameed and Rattan Lal (1971) on cabbage, cauliflower and knol-khol crops. Anonymous (1960) fixed its tolerance limit 8 ppm on cereals and oilseeds.

For the control of jassids, bugs and other sucking insect pests of paddy, generally malathion in 0.05% concentration at 1000 litres per hectare is used. But information on the deterioration of malathion residues on paddy crop is lacking. Kalode (1969) reported that no measurable residues of malathion could be detected on paddy crop (Taichung Native-1) after 48 hours of application of 0.05% concentration malathion spray.

A study on spray deposits was undertaken by chemical assay method to obtain precise information regarding the persistence of malathion residues on paddy crop, under field conditions.

The experiment was laid out in randomised blocks at Government Usar Reclamation Farm, Chakeri, Kanpur. Each treatment was replicated 4 times. Malathion, in 0.05%, 0.1% and 0.15% concentrations was sprayed @ 1000 litres/hectare on Saket-3 variety of paddy. Spraying was done on the point of slight run off, when grains of the ears were at milk formation stage.

Foliage and ears of paddy plants were plucked one hour, and 1, 2, 3, 5, 7 and 10 days after spraying. Dried leaves and ears of each sample were

| 5                    | Nil                 | ..                   | Nil                  | ..                   | Nil                  | ..                   |
| Half life (in days)  | 1.3                 |                      | 1.6                  |                      | 2.1                  |                      |
| Regression equation  | $Y = 1.546 - 0.43x$ |                      | $Y = 1.648 - 0.405x$ |                      | $Y = 1.754 - 0.356x$ |                      |

homogenised and measured quantity of finely powdered leaves and ears were used for extraction in Soxhlett extraction apparatus, using carbon tetrachloride as the solvent. The extract was concentrated under reduced pressure and used for the determination of malathion by the technique described by Gunther and Blinn (1955) with the help of Klett Summerson Photoelectric Colorimeter. The log residues (half-life values) of malathion (Fig. 1) was calculated with the formula suggested by Gunther and Blinn (1955).

It is clear from Table I, that as the duration after spraying increases, residues from all the concentrations, viz., 0.05%, 0.1% and 0.15% decreases. The increase in concentrations of malathion spray follows with the increase in residues.

The reduction in the initial deposits of malathion from 0.05% conc. was 12.0 and 5.0 ppm after 1 and 2 days respectively; while in 0.1% conc. it was 15.0 and 7.5 ppm after the same time interval; and for 0.15% conc. it was 21.50 and 13.50 ppm for 1 and 2 days after spraying respectively in all the concentrations. It is significant to note that in all the concentrations on the 1st and 2nd day after spraying, there is about 67-86% reduction on the initial deposits. Malathion residue reaches well below the tolerance limit of 8 ppm within 3 days and completely ineffective within 5 days after spraying on paddy plants.

Half life values of different concentrations of malathion were 1.3 days for 0.05%, 1.6 days for 0.1% and 2.1 days for 0.15%. Dewan *et al.* (1969) have also obtained almost similar results on cowpea fruits and grains.

It reveals that the spraying of malathion in 0.05%, 0.1% and 0.15% concentrations has very little applied interest, as it rapidly decomposes on paddy plants.

FIG. 1. Log residues Malathion for different concentrations.

Malathion in 0.05%, 0.1% and 0.15% concentrations was sprayed on paddy @ 1000 litres/hectare to study its residual effect. It revealed that the reduction in the toxicity of malathion was 68-87% even on 2nd day of spraying. It reached below 8 ppm within 3 days in all the concentrations. Hence it is not worthwhile to spray malathion on paddy plants.

### EMS INDUCED MUTATION IN *AMARANTHUS TRICOLOR* L.

MOST of the species of *Amaranthus* L. are cultivated as pot herbs or for their grains. Some of these are polymorphic in nature and certain horticultural varieties have been developed which are of ornamental value. *Amaranthus tricolor* L. is a highly polymorphic one with number of varieties recognised under it. The most variable character in this group of plants is the development of anthocyanin. The pigment develops in various parts of the plants such as stems, petioles, leaves and inflorescences. In the leaves it may develop on the margin or as patches on the lamina giving ornamentations. In some varieties the whole plant is red. As no chromosomal variation was noticed in these forms it was suggested<sup>4</sup> that the development of anthocyanin is under genic control though seasonal variations also affect the development of the pigment within a variety or a species. In a recent attempt to test the mutability in different species of *Amaranthus* L., a fully red coloured variety of *A. tricolor* L. was selected at the first instance.

The seeds were treated with 0.1%, 0.2% and 0.4% of EMS (Ethyl Methane Sulphonate) by soaking for 4 hours in each with a presoaking of 2 hours in distilled water. Then the seeds were thoroughly washed with water and were grown in earthenware pots as well as in petri dishes. A control set was maintained in soaking the seeds in distilled water for 6 hours. Initially the percentage of germination in each concentration was determined and it was found to be 61.0% in 0.1%, 16.0% in 0.2% and 2.2% in 0.4% of EMS as a contrast to 81.1% in control. Thus 0.2% and 0.4% EMS were highly lethal for these seeds. Of the total of 421 seedlings, 5 plants were mutants in M<sub>1</sub> generation which could be distinguished by the complete suppression of anthocyanin development. These seedlings were appearing fully green as a contrast to the complete red colour in normal seedlings. Of these two were from the group treated with 0.1%, 2 from those treated with 0.2% and 1 from those treated with 0.4% EMS but the last one did not survive. However, there were as many as 138 seedlings which showed partial greenness which soon turned red probably due to the recovery of the anthocyanin development. But the complete green seedlings remained green for a pretty long time and though later they developed anthocyanin they could not compete with the normal ones as noticed visually and through spectrophotometric analysis<sup>1</sup>. The anthocyanin was extracted with cold 0.1N HCl for 24 hours. The amount of anthocyanin present in the leaves was estimated by measuring the absorption of the extract at 510 nm (Table I). Thus like chlorophyll mutations<sup>2,3</sup>, anthocyanin development seems to be affected by mutagenic treatment. The four mutants were also marked out from rest of the plants as well as from the control in various other morphological characters (Table II).

TABLE I

Relative anthocyanin content of the leaves of normal and mutant plants

| Sl. No. | Type     | Amount of anthocyanin*    | % of control | % decrease |
|---------|----------|---------------------------|--------------|------------|
| 1.      | Normal   | 0.29<br>(range 0.32-0.26) | 100          | ..         |
| 2.      | Mutant-1 | 0.16                      | 55           | 45         |
| 3.      | Mutant-2 | 0.14                      | 48           | 52         |
| 4.      | Mutant-3 | 0.10                      | 34           | 66         |

\* O.D. at 510 nm per 10 mg fresh weight of leaf.

The cytological analysis of the mutants made through the study of the pollen mother cells also revealed the formation of multivalents in all the mutant plants. While quadrivalents were frequently

TABLE II

| Flowering (days from soaking) | .. | Early (45 days)                                    | Late (70 days)                                      |
| Seed sterility                | .. | High (69·79 %)                                     | Low (40·19%)  |

noticed in the EMS induced mutant of *Amaranthus dubius* Mart. ex Thell.<sup>2</sup> higher multivalent associations involving 2-7 bivalents have been met with in different cells in these mutants. Such types of meiotic irregularities, however, have been reported<sup>5</sup> to be rare in EMS treatments and more predominant in MES and myleran treatments. The meiotic irregularities might be responsible for the high seed sterility observed in the mutants.

The authors are grateful to Prof. B. Padhi, for providing facilities and encouragements and University Grants Commission, New Delhi, for financial assistance. The authors are also indebted to Dr. R. N. Misra, Cytogeneticist, C.R.R.I., Cuttack, for supplying the chemical and giving valuable suggestions.

#### RADIATION INDUCED VARIABILITY IN QUANTITATIVE TRAITS OF JOWAR (*SORGHUM VULGARE*, SNOW.)

MUTAGEN treatment generally induces and increases genetic variability in population. Oka<sup>1</sup> observed significant changes in the means and variability of quantitative traits due to irradiation in rice. Radiation induced variability of several polygenic traits in wheat 'has' also been observed<sup>2</sup>. The increased

genetic variability due to induced mutation may permit selection for desirable traits<sup>3</sup>. With most of the sorghum hybrids having reached grain yield stagnation and others being susceptible to diseases like mildew, leaf blight, leaf spot, and rusts, it is imperative to induce variability in polygenic traits in desirable direction through mutation breeding so as to break the ceiling of yield and improve ideotype in this crop. The present note reports the response of gamma-irradiation in shifting the mean values of several quantitative traits in  $M_1$  generation.

Dry seeds of seven inbreds (CS 3541, 2219 B, IS 3691 B, IS 84, R-16-3, 2077 B and Swarna) and five recently released hybrids (CSH-1, CSH-2, CSH-3, CSH-4 and CSH-5) were treated with gamma-irradiation from  $C_{60}$  source at IARI, New Delhi, with 10 Kr, 20 Kr, and 35 Kr doses. The treated seeds were sown in the field within twenty-four hours of treatment. The observations were made on twenty-five randomly selected plants for each treatment. The height of the plant is reduced due to gamma-irradiation in all the varieties as compared to control, the pronounced reduction in height appeared at 20 Kr and 35 Kr doses. The number of effective tillers per plant was also decreased, the 35 Kr dose reduced the tiller number markedly (30%). There was not much effect of irradiation on the leaf number per plant. The peduncle length in  $M_1$  generation exhibited a decreasing trend in all the varieties excepting Inbred 2219 B and hybrid CSH-2, where no change in peduncle length was noticed. The variety IS 3691 B seemed more sensitive to 20 Kr and 35 Kr doses in comparison to other varieties where flag leaf was just attached to the panicle. All the three doses of gamma irradiation appeared to induce late blooming. The pollen viability and seed fertility data are presented in Table I and these factors decreased significantly in  $M_1$  plants in all the varieties. The 35 Kr dose, however, showed marked effect in hybrid and inbred backgrounds.

| 20 Kr                 | .. 79     | 69    | 62    | 59    | 83    | 79     | 75    | 76   | 67      | 87     | 74   | 56     |
| 35 Kr                 | .. 66     | 62    | 47    | 56    | 52    | 71     | 31    | 47   | 60      | 65     | 49   | 42     |

The results suggest a general shift in the mean values in negative direction with regard to the quantitative traits. Some decrease in the biological values of  $M_1$  populations of Sorghum with regard to germination, seedling growth and seed fertility due to the treatment of two chemical mutagens (NMS and MNG) has been observed<sup>5</sup>. A high frequency of diverse types of plant abnormalities were also observed in  $M_1$  generation. More frequent amongst them were chlorophyll streaks, unequal half of leaf blades, thick leaves, and stunted growth. Such  $M_1$  plant abnormalities have also been reported by Shree Ramulu and Goud<sup>7</sup>. There did not seem to be any dependence of mutagenic effects on the backgrounds of the genotypes as the hybrids and inbreds showed similar response to irradiation treatments in  $M_1$  generation in shifting the mean values of quantitative characters. A few dwarf and erect leaved mutants in  $M_2$  generation have been identified. Work on further generations is in progress.

#### NEW LEAF AND FRUIT GALLS ON *BASSIA LONGIFOLIA* LINN. (SAPOTACEAE)

GALL formation in plants, belonging to the family Sapotaceae in India, appears to be restricted to the genera *Bassia* and *Mimusops* involving two species each, *B. longifolia* Linn., and *B. latifolia* Roxb., *M. elengi* Linn., and *M. hexandra* Roxb. Two midge galls and a chalcid gall are reported from *B. latifolia* while in *B. longifolia* the causative agent in all the four reported galls appear to be midges (Mani<sup>1-3</sup>). Recent observations on gall formation in *B. longifolia* revealed the presence of two more galls—a leaf gall by a midge and a fruit gall by a chalcid, both hitherto unrecorded.

The leaf galls (Fig. 1) appear simple, spherical, pellet-like, pale brown, solid, fleshy, hard, indehiscent, persistent, hypophyllous, 2–3 mm in diameter placed at the ends of the primary lateral veins or of other veinlets, 0.5–1 mm within the margin of the lamina and visible also from the adaxial laminar side. Each leaf bears 2–17 well spaced galls near one or both margins or 2–6 in a closely arranged row. Rarely two adjacent galls may become confluent and appear as a single bilobed structure. The distribution of the galls on either side near the laminar margins is mostly unequal, being of

the order 0-2, 2-5, 0-6, 8-2, 3-8, 17-0, etc., and very rarely subequal.

The bulk of the gall appears to be filled with parenchyma bearing numerous tanniniferous cells, with the nutritive zone surrounding the central circular larval chamber devoid of them. Between the parenchymatous and the nutritive zones is a narrow, 2-3 cell thick, concentric zone of small parenchyma cells, each with a crystal. The vascular strand shows divergently scattered xylem elements terminating at the base of the gall.

Young galled fruits of *B. longifolia* (Fig. 2), appearing about late May, were seen to drop prematurely due to galling by an unidentified chalcid. The weakly lobed, globose fruit galls bear a dense covering of rusty brown hairs. Numerous exit holes—their number depending on the number of emerging adult chalcids—mostly circular, about 1 mm or a little less in diameter, occur around the swollen base of the style (Fig. 2) and also around the base and rarely on the sides of the galled fruit.

FIGS. 1-2. Fig. 1. Pellet-like galls near the leaf margins of *Bassia longifolia* (also seen are the midrib and laminar galls). Fig. 2. Normal and galled fruits (of the same age) of *Bassia longifolia*. Left—normal fruit; middle—galled fruit with dense covering of hairs; right—top view of the galled fruit showing the exit holes.

About 9-40, long often curved or oblique larval chambers of varying sizes with one adult chalcid

or its larva in each, occur inside the galled fruit. In cross-sections, the larval chambers appear circular surrounded by a 6-8 cell thick sclerotic zone and scattered irregularly in the parenchymatous, broadened septa of the galled fruit. Six to nine ovary chambers, usually large and radially arranged, are represented in the galled fruit by as many narrow radiating gaps, lined with one regular row of tanniniferous cells and extending upto half the distance from the centre of the galled fruit.

In heavily infested galls, seed formation is totally suppressed; but in the case of mild infestation (mostly confined to the top of the fruit) one normal seed may develop. It is significant to note that the normal fruits are 1-2 seeded or sometimes 3-4 seeded, indicating that the development of other seeds is being suppressed at an early stage of fruit formation.

Further work on the anatomical aspects of the galls is in progress.

I express my deep sense of gratitude to Prof. T. N. Ananthakrishnan, Loyola College, Madras, for the critical reading of the manuscript and the encouragement and also to Prof. M. S. Mani, St. John's College, Agra, for confirming these galls as new and for identifying the gall makers.

#### AERIAL ROOTS IN *CUCURBITA* L.

HITHERTO, aerial roots in Cucurbitaceae have been reported only in *Momordica*<sup>1</sup>, *Luffa*<sup>2</sup> and *Siolmatra*<sup>3,4</sup>. This note reports the occurrence and describes the anatomy of aerial roots in *Cucurbita maxima* Duchesne.

The plant produces aerial roots at the nodes, below the tendrils. The whitish roots which arise on the upper nodes grow to a length of about 15.0-20.0 cm and measure about 1.5-2.0 mm across. Usually, only one root per node arises, on the upper nodes. They dry out gradually and wither away, apparently being functionless. More than one root per node arise from the lower nodes. They produce lateral roots and develop an extensive system when they reach the ground.

The aerial root is endogenous, arising from the interfascicular region of the stem (Fig. 1). Its epidermis is one cell thick (Fig. 2). The epidermal

cells of the roots, which penetrate the soil, produce root hairs. The cortex is parenchymatous with intercellular spaces. The endodermis and pericycle are each one cell thick. The stele is radial and has four to eight exarch protoxylem strands, alternating with as many patches of phloem. In t.s. (Fig. 2) the phloem patches are large and semicircular in outline. The roots exhibit secondary growth, which is similar to the pattern observed in the normal terrestrial roots of this plant. Periderm formation takes place in older roots and the phellogen is of superficial origin.

FIGS. 1-2. Fig. 1. Part of stem showing aerial roots. A—aerial root, T—tendrils. Fig. 2. Part of t.s. of an aerial root from an upper node.

The roots on the upper nodes die away. Experiments are under progress in this department, to find out whether this intrinsic capacity of this vegetable crop plant could be exploited successfully for fast vegetative propagation.

#### CYTOLOGICAL STUDIES IN *GALPHIMIA GRACILIS* BARTLING

As far as is known, cytological work in the family, Malpighiaceae is restricted to the report of basic chromosome number for *Stigmatophyllon* and *Banisteria*<sup>1</sup>. In view of lack of definite cytological information in the family, it was considered desirable to make a more detailed cytological study of some of the locally available Malpighiaceae. The present communication deals with meiosis in *Galphimia gracilis* (*Thryallis gracilis*) Bartling., a handsome ornamental shrub bearing yellow flowered panicles. In this study, the material collected from the Government College for Women, Guntur, was fixed in 1:3 acetic-alcohol for 24 hours and smeared in acetocarmine.

From the squashes the haploid chromosome number for this species is found to be 12 ( $n=12$ ). Of the 160 cells analysed at diakinesis 79.9% of them manifested 12 bivalents and 10.1% showed a comparatively smaller extra chromosome which appeared to be a B-chromosome (Fig. 1); this being the first report for the family. In about 10% of these cells univalents varying from two to four in number were observed. The bivalents possessed one or two chiasmata and the frequency per cell ranges from seventeen to nineteen. Terminalization coefficient (TC) at diakinesis is 0.33. This low T.C. may be attributed to either terminal non-homology or some other cause. Normal segregation of 12:12 at anaphase I was observed in 65% of microsporocytes. Frequently cells with late disjunction, bridges, bridgefragment configuration (Fig. 3) and lagging univalents (Fig. 2) were also noticed both at anaphase I and II and telophase I and II. Formation of more than four spores (polyspory) was also recorded in about 10% of the dividing microsporocytes (Fig. 4). Possibly this

FIGS. 1-4. Fig. 1. Diakinesis showing 12 II and one B-chromosome,  $\times 1528$ . (B-chromosome arrowed). Fig. 2. Anaphase II with laggards and chromatin bridge,  $\times 1470$ . Fig. 3. Telophase II showing laggards and disjunction bridge,  $\times 1469$ . Fig. 4. Microsporocyte with 5 microspores,  $\times 1785$ .

may be due to the occurrence of lagging chromosomes which may subsequently organise into a micronucleus at telophase I and II. Another feature of interest is the occurrence of dimorphic pollen grains. Of the 600 pollen grains analysed for this feature, 42.6% were comparatively bigger measuring 20.0 to 26.0 microns while 14% were smaller ranging in size from 12.0 to 16.0 microns. In both the cases the pollen grains at anthesis were usually 2-celled, although four nucleate condition was not infrequent and this feature may be due to the precocious mitotic division of the microspore nucleus. Pollen sterility to an extent of 43.6% was recorded. The meiotic abnormalities like lagging, unequal distribution of univalents, bridges with fragments and polypory perhaps account for the partial pollen sterility.

The authors thank Professor A. S. Rao for facilities and taking microphotographs. Our thanks are also due to Dr. B. G. S. Rao for providing literature.

#### ENERGY CONSERVING EFFICIENCY OF WHEAT IN RELATION TO PLANT COMPETITION

ALTHOUGH the data on energy relations of a number of temperate ecosystems have been published<sup>1-4</sup> so far, the information regarding the terrestrial ecosystems in India is very meagre<sup>5-6</sup>. The present study was carried out with wheat (*Triticum aestivum* L. var. K-68). The crop was grown in two cultivated fields of village 'Moglaha', 7 km north of Gorakhpur University Campus. The water and nutrient supplies were kept above optimum. In one of the fields, designated as Pure Stand (PS), the competing weeds were removed at fortnightly interval, while in the other field, designated as Mixed Stand (MS), the competing weeds were allowed to grow with the crop plants. Net dry matter production of the crop was evaluated by harvesting the plants from five quadrats (25  $\times$  25 cm) for aboveground parts and by digging five soil monoliths (25  $\times$  25  $\times$  30 cm) for underground parts at monthly intervals throughout the growing period and by summing up the positive differences

in the plant biomass. The calorific value of the plant material was estimated using a bomb calorimeter. The energy captured by the vegetation was calculated by multiplying the net dry matter production with its calorific equivalents. The energy conserving efficiency was evaluated by expressing the energy capture as percentages of half of the solar radiation during the period<sup>7-8</sup>.

TABLE I

Energy conserving efficiency (%) of wheat plants in pure stand and mixed stand at different stages of growth

| Growth stages | Age of crop in weeks | Solar energy at land surface (K cal/m <sup>2</sup> ) | Energy conserving efficiency(%) |             |
|---------------|----------------------|--|---------------------------------|-------------|
|               |                      |  | Pure stand                      | Mixed stand |
| Seedling ..   | 4                    | 116400   | 0.55                            | 0.46        |
| Vegetative .. | 8                    | 101400   | 4.19                            | 3.17        |
| Earing ..     | 12                   | 106200   | 11.34                           | 7.54        |
| Maturity ..   | 16                   | 131400   | 3.13                            | 2.63        |
| Harvest ..    | 20                   | 144300   | 0.11                            | 0.09        |

The data set in Table I reveal that the energy conserving efficiency of wheat plants in both the stands increased with the advancing age. But after attaining a certain maximum value it decreased. The maximum value at the earing stage may be due to the maximum net dry matter production at the same stage. This is in conformity with the findings of Dwivedi<sup>5</sup> and Gupta<sup>6</sup>, who have observed maximum energy conserving efficiency at the time of maximum net dry matter production in the case of *Triticum aestivum*, *Dichanthium annulatum* and *Cynodon dactylon* respectively.

The statistical analyses exhibit that the energy conserving efficiency of wheat plants was significantly lower in MS than that in PS ( $t = 1.541$ ;  $P = 0.2$ ). The possible cause for such a reduction may be due to greater competition for light, water and nutrients by weeds in MS. This finding supports the work of Sahai and Das<sup>9</sup>. Similarly, Dwivedi<sup>5</sup> has also observed less energy conserving efficiency in wheat plants of MS than that of PS.

Grateful acknowledgement is made to Prof. K. S. Bhargava for providing facilities and to Rev. Dr. Frank B. Rehnstrom of Sweden for his financial assistance to one of us (L. K. D.).

#### FATAL EFFECT OF INSECTICIDE-TREATED APHIDS ON COCCINELLA SEPTEMPUNCTATA L.

CONSIDERABLE loss of population of *Coccinella septempunctata* L., an important predator of aphids, may occur when an insecticide is applied to control aphids on crops. The predator suffers in two ways, (i) by coming in direct contact with the insecticide, and (ii) by feeding on aphids poisoned with insecticides. The mortality of the predator by the former factor has been determined by several workers but no work on the latter has been reported so far. The present investigation was, therefore, undertaken to determine the mortality of adult *C. septempunctata* by feeding them on aphids treated with different insecticides.

Fresh mustard leaves heavily infested with aphids were sprayed with one ml of several insecticides in separate petri dishes under a potter's spraying tower at 24 mm mercury pressure. They were allowed to dry for five minutes under a ceiling fan. Sufficient number of aphids were removed with a brush and transferred to unsprayed leaves kept in clean petri dishes. Ten adult beetles from a laboratory culture were released in each petri dish at 20°-25° C. The treatment were replicated five times. Old leaves in each petri dish were replaced by new ones after every 24 hours. The mortality counts of the predator were recorded after 12, 24, 48 and 72 hours. The per cent mortality data thus obtained were corrected by using Abbott's (1925) formula and subjected to statistical tests.

It is evident from Table I that endosulfan, chlorfenvinphos and menazon gave the lowest mortality of the adults of *C. septempunctata*, when aphids

| Methyl demeton 0.025 ..        | 40.0 (39.1)   | 40.0 (39.1) | 62.0 (52.1) | 82.0 (65.6) |
| C.D. at 5% ..                  | (9.6)   | (15.5)      | (11.8)      | (11.9)      |

The figures given in parenthesis are the means of angular transformation of per cent mortality in the five replications.

sprayed with these insecticides were fed to them, irrespective of testing intervals.

Aphids sprayed with malathion and diazinon resulted in a high mortality of the beetles at all the testing intervals.

Thus endosulfan, chlorfenvinphos and menazon were the least toxic and malathion and diazinon are the most toxic to the adults of *C. septempunctata*.

The authors are thankful to Prof. D. S. Gupta, for providing necessary facilities and to Shri B. K.

Anand, Division of Entomology, IARI, for identifying the insects.

## SHORT SCIENTIFIC NOTES

### A Note on Prehistoric Cultural Evidence from Tirupati, Andhra Pradesh

This study presents new evidence of prehistoric importance of Tirupati, Chittoor District, based on the author's explorations from early 1973. The western outskirts of Tirupati starting from Sri Venkateswara University campus towards north up to Seven Hills have prehistoric sites with hand axes, cleavers, flakes and a few cores.

Site I is at the rear end of S.V. University Library. Site II is a canal bed on the northern side of S.V.U. Library and the first site. It extends for 12 furlongs in an East-West direction. Here the tools were found at the depth of 4 to 6 feet. Site III is inbetween the second site and the foot of the Seven Hills where a water tank is under construction. All three sites are located within a range of one mile.

It is suggested that this is an evidence of Lower and to a certain extent middle paleolithic cultures in this area. The workmanship and technique of the latter is thought to be 'levellois'. The variety of tools in the three different sites denotes gradual change with improved technology from sites I to III. All the tools are made of Quartzite stone. Its colour varies from reddish brown to grey. The second and third site tools are fresh and original sharpness is retained. Hand axes include different types such as pyriform, conical, cordate, ovate and the like as shown in Table I.

TABLE I

| Category of tools | Site I | Site II | Site III | Remarks                               |
|-------------------|--------|---------|----------|---------------------------------------|
| Hand axes         | 5      | 3       | 4        | Pyriform, Conical, Cordate, and Ovate |
| Cleavers          | 2      | 1       | 3        | Chisel and Rectangular                |
| Flakes            | nil    | 4       | 6        | End and side flakes                   |
| Cores             | nil    | nil     | 3        | ..                                    |

These are dated back to 50 to 75 thousand years based on preliminary analysis.

S.V. University,  
Tirupati 517502 (A.P.), July 24, 1974.

### *Spegazzinia sundara* from *Datura metel*

During a regular survey of leaf spot diseases of common medicinal plants, the author obtained a species of *Spegazzinia* which closely resembles

*S. sundara* Subram. Earlier this fungus was recorded on dead bamboos and dead leaves of *Ananas comosus*<sup>1</sup>. Another species, i.e., *S. ornata*<sup>2</sup> also has been recorded on dead leaves.

The present species of *S. sundara*, however, is peculiar in being associated with leaving leaves of *D. metel* Linn. The fungus makes very luxuriant growth on defoliated leaves. Reports regarding the fungus are however very limited. Available literature shows that the fungus was not obtained earlier from *D. metel*.

The author expresses his grateful thanks to Dr. K. S. Bilgrami for laboratory facilities.

### Induced Polyploidy in Indian Spinach

Indian spinach (*Basella alba*) belonging to the family Basellaceae is a glabrous, succulent herb, mainly used as a green vegetable<sup>1</sup>. Literature on the improvement of this crop to isolate and establish polyploids with enhanced foliage is scanty. Hence an attempt was made to induce polyploidy in this crop and results are summarised in this note.

Growing tips of five day old seedlings of *Basella alba* were treated with 0.25% aqueous colchicine for 72 hours. Out of ten seedlings treated, one plant exhibited distinct gigas characters, characteristic of polyploids and the cytological studies confirmed its autotetraploid nature. Observations on length and breadth of leaves, frequency and size of stomata, size and sterility of pollen grains were gathered from this plant and compared with the normal diploid. The data are presented in Table I.

TABLE I

| Type of plant | L/B ratio of leaves | No. of stomata/unit area | Size of stomata  |                   | Diameter of pollen grains ( $\mu$ ) | Pollen sterility (%) |
|---------------|---------------------|--------------------------|------------------|-------------------|-------------------------------------|----------------------|
|               |                     |                          | Length ( $\mu$ ) | Breadth ( $\mu$ ) |                                     |                      |
| Diploid       | 1.21                | 17.16                    | 3.83             | 2.23              | 2.70                                | 5.00                 |
| Tetraploid    | 1.10                | 12.86                    | 4.03             | 2.25              | 3.20                                | 11.69                |

In general, the autotetraploid was characterised by larger, thicker and succulent leaves, larger stomata and pollen grains. But the number of stomata per unit area and mean pollen fertility were lower than the normal diploid.

Meiosis was studied in the polyploid plant by fixing flower buds of appropriate size in 1:3 acetic alcohol. Chromosome counts made from anther smear preparations, stained with 2% acetocarmine, revealed the autotetraploid nature of the plant, with  $2n = 96$  chromosomes as against  $2n = 48$  in the normal diploid. A total of 41 cells were scored at Metaphase I and Anaphase I, to study the chromosome behaviour. The frequency of quadrivalents and trivalents was much less compared to bivalents and univalents. The mean chromosomal configurations per cell were: quadrivalents 0.31, trivalents 0.052, bivalents 34.84 and univalents 25.21. In spite of large number of univalents observed during Metaphase-I, fairly high degree (68%) normal disjunction of chromosomes to 48:48 was noticed during Anaphase-I, resulting in high percentage of fertile pollen. However, laggarids were also observed at Anaphase-I.

The autotetraploids of *Busella alba* appears to be interesting in view of its high pollen fertility, more thick and succulent leaves. Besides, it can be propagated vegetatively also. Further studies on breeding behaviour and critical evaluation of autotetraploid are in progress.

We are grateful to Dr. N. P. Patil, Director of Research, U.A.S., Bangalore, for his encouragement.

## ANNOUNCEMENTS

### Award of Research Degrees

Karnatak University, Dharwar, has awarded the Ph.D. degree in Mathematics to Shri Hegde Venkatramana Subraya, for his thesis entitled "Topics in Global Differential Geometry with special reference to Integral Formulae and their applications"; and to Shri Subhas Sangayya Bhusnoormath, for his thesis entitled "Exceptional Values of Meromorphic Functions"; Ph.D. degree in Chemistry to Shri Gurusiddhaya Shivayya Gadaginamath and Shri Muralidhar Gurachar Purohit, for their thesis entitled

"Synthetic Studies in the Indole Field" and "Studies in the Indole Field." respectively.

The M. S. University of Baroda has awarded the Ph.D. degree in Geology to Shri Ramachandra Anant Chansarkar, for his thesis entitled "Drainage and Slope Analysis of Kosi Basin in Central Kumaon with Special Reference to the Geological Controls"; Ph.D. degree in Chemistry to Shri Dineshchandra Ochhavlal Shah, for his thesis entitled "Synthesis of Phenanthro Indolizidines and Nitrogen Mustards as Anti Cancer Agents";

Sri Venkateswara University, Tirupati, has awarded the Ph.D. degree in Mathematics to Shri J. Hanumanthachari, for his thesis entitled "Some Contributions to the Theory of Arithmetic functions"; Ph.D. degree in Physics to Shri V. Kesava Reddy, for his thesis entitled "Studies in Solid State Physics Third-order elastic moduli of Carbon and Alloy Steels"; Ph.D. degree in Zoology to Shri P. Murali Mohan, for his thesis entitled "Studies on the Physiological and Bio-chemical aspects of aestivation of a selected gastropod, with special reference to nervous system"; Ph.D. degree in Botany to Shri K. Subramanya Sastry, for his thesis entitled "Studies on Mosaic Virus Disease of Brinjal incited by a strain of tobacco ring spot virus".

Utkal University, Bhubaneswar, has awarded the Ph.D. degree in Physics to Shri M. K. Parida, for his thesis entitled "Description of High Energy Phenomenon"; Ph.D. degree in Chemistry to Smt. Nivedita Mullick, for her thesis entitled "Reactivity of Co-ordinated Ligands"; Ph.D. degree in Botany to Shri Ch. Narasinga Rao and Shri S. N. Ratho, for their thesis entitled "Physiological studies on Tillering Potential in Rice" and "Cytogenetical studies on African cultivated rice (*Oryza glaberrima* Steud) with special reference to the Exploitation of this germplasm" respectively; Ph.D. degree in Zoology to Shri Bimbadhar Nayak, for his thesis entitled "Studies on the Male Germinal Chromosomes of thirty-one species of moths and butterflies (*Lepidoptera*)".

Tamil Nadu Agricultural University, Coimbatore, has awarded the Ph.D. degree in Agriculture to Shri A. Abdul Kareem, for his thesis entitled "Studies on the Antifeeding effects of two organotin compounds, triphenyltin acetate and triphenyltin hydroxide on *Spodoptera litura* F., *Pericallia ricini* F. and *Spomopteryx subsecivella* Zell (Lepidoptera); to Shri M. Gopalan, for his thesis entitled "Studies on Feeding behaviour of Salivary secretions of ragmus importunitas distant (Hemiptera: Miridae) and its influence of the physiology of Sunnhemp, *Crotolaria juncea* L."; to Shri K. R. Ramaswamy, for his thesis entitled "Studies in the Genus *cenchrus* L.".

## REVIEWS AND NOTICES OF BOOKS

Annual Review of Astronomy and Astrophysics (Vol. 12). Edited by G. R. Burbidge, D. Layzer and J. G. Phillips. (Annual Reviews, Inc., 4139, Camino Way, Palo Alto, California 94306), 1974. Pp. 495. Price U.S.A. \$12.00 ; Foreign \$12.50.

The present volume contains seventeen articles. Of these one is on comets, one on the Moon, and three on the Sun. The remaining ones deal with compact X-ray sources, cosmic ray propagation in the Galaxy (collective effects), coherent molecular radiation, large scale dynamics of the interstellar medium, equation of state at ultra high densities, post-main sequence evolution of single stars, the chemically peculiar stars of the upper main sequence, radio radiation from interstellar molecules, the spectra of supernovae, planetary nebulae, nucleo-cosmo-chronology and the origin of light elements.

El-Baz discusses the lunar surface geology in the light of lunar samples obtained during the various moon probes (manned and unmanned). Some interesting photographs accompany the article. Gilman, in his article on solar rotation, discusses in a lucid manner the importance, nature and theories of solar rotation and enumerates the interesting problems that need to be investigated. The article on the solar x-ray spectrum concentrates on wavelengths less than 25 Å. This spectral range is relevant only for the high temperature coronal plasma, in particular active regions and solar flares. Stein and Leibacher discuss in a systematic manner, the various wave modes in the solar atmosphere. An important feature of this article is the description of wave mode properties in terms of the wave number-frequency diagram.

X-ray astronomy was last reviewed in these volumes in 1967. Since then the most spectacular progress has been made in the area of compact x-ray sources. It has been found that a large fraction of the compact x-ray sources consists of members of binary systems. This implies that studies of x-ray stars can provide us with considerable information about the dynamics of binary systems and the properties of compact objects. Litwak, in his review on coherent molecular radiation, discusses strong masers of OH and H<sub>2</sub>O. These masers are important to our understanding of regions of density and size that are intermediate between those of typical interstellar clouds and those of planets and stars. Kaplan and Pikelner

discuss the development of spiral structure and star formation based on large scale dynamics of the interstellar medium. Observational evidence for the theoretical results is briefly reviewed.

Canuto's paper on the equation of state at ultra high densities is the first of the two review articles. The first part concerns the density range  $10^6 \leq \rho \leq 5 \times 10^{14} \text{ g cm}^{-3}$ . The second article is expected to cover the region  $\rho > 5 \times 10^{14} \text{ g cm}^{-3}$ . In view of the numerous mathematical details, this article would appeal only to those who are actively involved in the study of neutron stars. In recent years the discovery of many molecules in space has acquired great importance for several reasons. A whole new field of interstellar chemistry has been ushered in by these discoveries. Zuckerman and Palmer review the radio radiation from interstellar molecules whose radio lines are intimately related to objects under study by optical and infrared observers.

The article by Oke and Searle concentrates on one important and neglected aspect of supernova research, i.e., the description, classification and interpretation of supernovae spectra. The following article on planetary nebulae by Miller traces the important developments since the last review which appeared in these volumes in 1964. In particular, there is a section on new subjects of infrared and radio studies.

Lastly, Reeves shows that by building up the evolutionary abundance curve (i.e., cosmic abundance versus time) of each isotope of the light elements (between hydrogen and carbon) we may obtain a great deal of information not only on their nucleosynthetic processes but also on the features of cosmic, galactic, stellar and even solar system physics that may have altered their abundances or their physical states.

P. K. RAJU.

### Books Received

*Ordinary Differential Equation—A First Course* (2nd Edition). By Fred Braver, John A. Nohel. (Addison-Wesley Pub. Co., Inc., Reading, Massachusetts 01867, U.S.A.), 1973. Pp. ix + 470.

*The Pteridophyte Flora of the Upper Gangetic Plain*. By N. P. Chowdhury. (Navyug Traders, Deshbandhu Gupta Road, New Delhi-5), 1973. Pp. xvi + 90. Price : Rs. 25.00 ; \$ 6.00 ; £ 2.50.

## INFORMATION TO CONTRIBUTORS

CURRENT SCIENCE is the Premier Science Fortnightly of India published by the Current Science Association, Bangalore and issued on the 5th and 20th of each month. All material intended for publication in CURRENT SCIENCE and books for review should be addressed to the Editor, *Current Science*, Raman Research Institute, Bangalore-560006.

The following types of Scientific Communications will be considered for publication :

- (i) Review articles on topics of major current interest not exceeding 4,000 words;
- (ii) Original Research Papers—not exceeding 2,000 words;
- (iii) Letters : These are brief reports of research of unusual and wide interest—they should not exceed 700 words in general;
- (iv) Short Scientific Notes—not exceeding 250 words.

Articles and papers should include a short abstract at the beginning.

References are indicated by superscripts in the text. The style of references should be *Journal* : The names of the authors, the journal, year, volume and page.

*Book* : Authors names, the title of the book, name and location of the publishers, year and page.

"Personal Communications" and "Unpublished Work" do not go into references and should be incorporated in the text. Acknowledgements should be brief.

Statements that the work is contribution No..... of the Institute, declarations that the Director has authorised publications, etc., are not printed.

"Series" papers are discouraged.

Manuscripts, to be submitted in duplicate, should be typewritten in double space on one side of the paper, carefully revised and in final form for printing. Illustrations should be minimum in number, drawn in black and white with Indian ink on bristol board. Figures are usually reduced to one column width, and the originals should be about twice their final size.

No reprints are supplied gratis, but can be had on request at cost per V.P.P.

Business correspondence, remittances, subscriptions, advertisements, reprints, exchange journals, etc., should be addressed to the Manager, Current Science Association, Raman Research Institute, Bangalore-560006.

---

### Subscription Rates :

Institutions : India Rs. 84.00; Foreign Rs. 150.00; \$ 20.00 or £ 8.00.

Individuals : India Rs. 24.00; Foreign £ 3.50; \$ 8.00.

### ABSTRACT

X-ray structural data of compounds containing the disulphide group  $X-S-S-Y$  in open chain molecules are examined with regard to their symmetry and conformation (as well as the chirality in the case of non-centrosymmetric crystals). When  $X$  and  $Y$  are identical and do not have any asymmetric centres in them, the space group in most cases has a centre of inversion or at least a mirror (glide), signifying the presence of both enantiomers. When  $X$  and  $Y$  have both asymmetric centres, the space group is necessarily non-centrosymmetric and enantiomorphous. Eight out of ten cases involving cystine and its derivatives indicate a preference for left chirality while pure cystine in two crystalline forms has right chirality.

### 1. INTRODUCTION

THE conformation of the disulphide group  $X-S-S-Y$  is of considerable interest from several points of view. Its conformation in open chain molecules is well known to be non-planar and dissymmetric similar to that of hydrogen peroxide with the torsion angle  $\theta$  around  $-S-S-$  being around  $\pm 90^\circ$ . In general, when  $X$  and  $Y$  are simple substituents and contain no asymmetric centres such compounds are optically inactive since the two conformers are readily interconverted by rotation around the single bond  $S-S$ , the energy barrier for rotation being small (about 5 kcal/mole). Attempts to resolve the two have therefore not been successful so far. However, if the groups  $X$  and  $Y$  are asymmetric, the two conformers need not have equal energy and consequently one may be preferred over the other. In fact, a typical example is the amino acid L-cystine which shows high negative optical rotation in solution in the visible region, contrasted with moderate positive values shown by most of the other L-amino acids. The high negative rotation of L-cystine has been attributed by Fredga (1950) to the dissymmetric disulphide group.

An earlier analysis by Hordvik (1966) was concerned with correlating the torsion angle  $\theta$  with the bond length  $-S-S-$  and the variation of bond order with the above angle. In the present paper we examine a different aspect of the results of X-ray analysis in the solid state, namely, (a) to study the symmetry and space group of the crystal structures and its dependence if any on the nature of the substituents; (b) When the groups  $X$  and  $Y$  contain asymmetric centres, to study the chirality of the  $-S-S-$  group in the solid state and to compare it with the ORD results in solution. In the latter case the compounds necessarily take up non-centrosymmetric enantiomorphous space groups

and hence the chirality can be established via the X-ray anomalous scattering method (Bijvoet, 1954). The compounds studied in the second category are mostly L-cystine and its derivatives. We exclude from this study compounds which have the  $-S-S-$  group in a ring system or in which  $-S-S-$  acts as a bridge.

### 2. ANALYSIS AND DISCUSSION OF DATA

#### 2.1. Groups $X$ and $Y$ with no Asymmetric Centre

Table I lists the crystal structures and the space group of compounds with  $X$  and  $Y$  containing no asymmetric centres. The first thirteen compounds have  $X=Y$  while the last two have  $X \neq Y$ . It is interesting to note that all but one of these thirteen crystallize in space groups which contain either a centre of inversion or at least a glide plane. This necessarily implies that both conformers exist in these structures. The only exception in the above group is diphenyldisulphide which takes up the enantiomorphous space group  $P2_12_12_1$  so that only one of the two conformers exists in a given crystal. It would be of interest to establish the absolute structures\* of the crystal, so also in the case of the non-centrosymmetric structures such as *p*-bromophenyl disulphide ( $Ccc2$ ).

\* X-ray anomalous scattering effects can be used in general, for any non-centrosymmetric crystal. Thus the effects may be detectable not only in enantiomorphous space groups but also in non-enantiomorphous crystals possessing symmetry element such as a mirror or glide. As has been pointed out elsewhere (Srinivasan, 1971), the term "absolute configuration" in such cases is rather misleading since it connotes, in the conventional sense, one of the non-superposable mirror images, and the term absolute structure would seem preferable. What is established in such cases is the absolute structure in relation to some physical property associated with directional asymmetry.

It is of interest to remark here that there was controversial discussion as to whether the space group of dibenzyl-lisulphide is Cc or C2/c [Dijk and Visser (1971); Einsphar and Donohue (1971) and Lee (1971)]. The use of anomalous scattering has resolved this problem (Srinivasan and Vijayalakshmi, 1972).

The spontaneous resolution observed in the case of diphenyl disulphide does not appear to be unique. Similar occurrences have been noted for example in inorganic disulphides (Foss, 1954) and also in organic peroxy compounds (Jeffrey *et al.*, 1964). In fact, the simplest of such a dissymmetric molecule is hydrogen peroxide (Srinivasan, 1970). It crystal-

lises in the enantiomorphous space group P4<sub>1</sub>2<sub>1</sub>2 or P4<sub>3</sub>2<sub>1</sub>2 (Abraham, Collin and Lipscomb, 1951)<sup>1</sup>.

While the enantiomorphous nature of the space group demands in all these cases, only one of the conformers to be present in a given crystal, the possibility of a single crystal containing microdomains of the enantiomorphous regions is not ruled out at least in a few cases where conditions are favourable. In fact, Sax and McMullan (1967) suggested the possible existence of such microdomains in the case of dibenzoyl peroxide considering the diffuse scattering intensity and the geometry of packing of the molecule in the unit cell. The above possibility may be verifiable by the use

of X-ray anomalous scattering technique, since the presence of equal amounts of each domain should give practically zero Bijvoet differences. This aspect is being pursued in this laboratory.

The last two compounds have  $X=Y$  and one of them takes up the enantiomorphous space group  $P2_12_12_1$ , while the other is centrosymmetric ( $P2_1$ ).

## 2.2. Group A, Y with Asymmetric Centres

Table II lists compounds with X and Y containing asymmetric centres. In all the cases excepting (6), the two groups are the same ( $X=Y$ ). As is to be expected they all take up non-centrosymmetric enantiomorphous space groups. Eight of the cases are L-cystine derivatives. Since the absolute configuration of the L-amino acid is known from X-ray anomalous dispersion method, this may be used as a reference to deduce the absolute conformation of the disulphide group in these crystals. In five of these cases, namely, (2) to (5) and (10), the chirality of the disulphide group is left (dihedral angles negative, around  $-80^\circ$ ) while in the two forms (1) and (7) of pure L-cystine alone it is right (positive, namely  $71^\circ$ ). Structural details for (6) are lacking. The two compounds (8) and (9) which are not cystine derivatives also have left chirality.

Thus, while all the derivatives of L-cystine indicate a preference for left chirality, for pure cystine alone (both hexagonal and tetragonal forms) the indication is to the contrary. A firm conclusion is therefore not possible although, if we ignore differences between the pure form and the derivatives, there is an overall preference for left chirality.

These may be taken to be in broad agreement with the results of ORD and CD studies in solution for disulphide group in ring system (Carmack and Neubert, 1967; Claeson, 1968; see also Linderberg and Michl, 1970). However these have to be reckoned with caution since our data concern primarily with open chain molecules. Semi-empirical methods for energy calculations may be expected to throw light on this aspect. These are being investigated and the results will be reported in due course.

# ULTRASONIC STUDY OF ASSOCIATION IN DICARBOXYLIC ACIDS

P. SUBRAHMANYAM AND C. RAGHUPATHI RAO

Department of Physics, Osmania University, Hyderabad

## ABSTRACT

Using Jacobson's free length theory, association factors in dicarboxylic acids have been calculated. For this purpose ultrasonic velocities and temperature coefficients of velocity of six acids in the homologous series are measured, using the composite ultrasonic interferometer designed in this laboratory. It is found that these acids obey Lagemann's rule, when association is taken into account.

THE ultrasonic behaviour of monocarboxylic acids has been reported earlier in a series of communications<sup>1-3</sup> from this laboratory and these studies are now extended to the homologous series of dicarboxylic acids with a view to studying the similarities and differences, if any, between these two groups of substances. Interesting results are obtained and several peculiar differences exist between monocarboxylic and dicarboxylic acids in their ultrasonic behaviour. Some of the important results are reported in this communication.

The temperature variation of ultrasonic velocity and density of these acids are shown in Figs. 1 and 2 respectively and their temperature coefficients are given in column 4 of Table I. The density of the dicarboxylic acids is found to decrease with increase in molecular weight, a behaviour similar to that of normal fatty acids<sup>3</sup>. The ultrasonic velocity decreases and temperature coefficient of velocity increases with increasing molecular weight in dicarboxylic acids, while the opposite is the behaviour in monocarboxylic acids<sup>1</sup> where velocity

\* Values are taken from *Hand Book of Chemistry and Physics* (1959) (Chemical Rubber Publishing Company, Cleveland, Ohio).

A composite ultrasonic interferometer<sup>4</sup> is used for determining ultrasonic velocities and temperature coefficients of velocity of six dicarboxylic acids, namely, glutaric, adipic, pimelic, suberic, azelaic and sebacic acids. As all the acids have high melting points (as shown in column 3 of Table I) the ultrasonic cell is kept in a special oil bath, whose temperature is regulated within  $\pm 0.3^\circ\text{C}$  by a mercury regulator, designed in this laboratory. The whole experimental set-up is well shielded to attain thermal equilibrium. As all the substances are either Reidell or B.D.H. samples of 'Analar' purity, no further purification is attempted. The velocities and their temperature coefficients are accurate to 1 in 1000. The densities are determined correct to the third decimal place, employing a specially designed dilatometer, which records changes in volume with temperature of a known mass of the substance.

increases and temperature coefficient of velocity decreases. The magnitude of  $(\Delta c/\Delta t)$  is smaller than that of monocarboxylic group of acids<sup>1</sup>.

Using the free length theory of Jacobson<sup>5</sup>, association factors of these acids have been calculated at  $170^\circ\text{C}$ , at which temperature, all of them are in the liquid state. According to Jacobson, the intermolecular free length ( $L_f'$ ) in liquids is related to the adiabatic compressibility ( $\beta_{ad}$ ) by the relation

$$L_f'^2 = K^2 \cdot \beta_{ad} \quad (1)$$

where K is a temperature dependent constant. The values of K at different temperatures upto  $50^\circ\text{C}$  have been given by Jacobson<sup>5</sup>. Wada<sup>6</sup> found that K is proportional to  $T^{1/2}$  where T is the temperature in absolute degrees and that  $(K/T^{1/2})$  is equal to a value of 36, with a variation of 1% in the temperature range  $0^\circ\text{C}$  to  $50^\circ\text{C}$ . Subsequently, Swamy<sup>7</sup>

FIG. 1. Temperature variation of ultrasonic velocities. A, Glutaric acid; B, Adipic acid; C, Pimelic acid; D, Suberic acid; E, Azelaic acid; F, Sebacic acid.

extended the validity of Wada's relation to higher temperatures. He found that  $(K T^{\frac{1}{2}}) = 36$  with a maximum variation of 1.5% upto a temperature of 157°C. Assuming the validity of Wada's linear relation between  $K$  and  $\sqrt{T}$  in the present study, the value of  $K$ , corresponding to the temperature of 170°C, is found to be equal to 758.

According to general definition of free length

$$L_f = \frac{2(V_T - V_0)}{[36\pi N V_0^2]^{1/3}} \quad (2)$$

where  $V_T$  is the volume at temperature  $T^\circ K$ ,  $V_0$

FIG. 2. Temperature variation of densities of dicarboxylic acids.

is the volume at absolute zero and  $N$  is the Avogadro Number.

Volumes  $V_{170}^0$  at 170°C for each liquid is calculated by evaluating its density  $\rho_{170}$  from the density graphs shown in Fig. 2.  $V_0$  is evaluated from Sugden's zero volume contributions. Values of  $V_{170}^0$  and  $L_f$  for different liquids are shown in columns 2.3 and 4 respectively of Table II.

The values of  $\beta_{ad}$  calculated for different liquids at 170°C and the values of  $L_f'$  calculated from equation (1) are shown in columns 5 and 6 respectively of Table II. A plot of  $L_f^2$  against  $\beta_{ad}$  for different liquids with  $K = 758$  is shown in

FIG. 3. Relationship between adiabatic compressibility and intermolecular free length of dicarboxylic acids at 170°C.

Fig. 3. All the evaluated points for different substances are found to lie below the straight line.

The association factors  $\alpha$  calculated for different substances by the relation

$$\alpha = \left[ \frac{L_f}{L_f'} \right]^3$$

are shown in column 7 of Table II. It is interesting to observe that association decreases with increase of molecular weight of the acid. When association is taken into account, Lagemann's rule<sup>9</sup> for normal liquids is obeyed by these substances as well and the product  $[\alpha M]^{\frac{1}{3}} \frac{L_f}{L_f'}$  is found to be constant as shown in column 8 of Table II with an average value of 39.08.

The first three members of the homologous series of dicarboxylic acids decompose near their melting points and as such their ultrasonic behaviour is being studied by solution method and their results will be published elsewhere.

## NUTRIENT COMPOSITION OF BARBADA OR MALMANDI (*INDIGOFEA GLANDULOSA*)

Y. G. DEOSTHALE AND V. NAGARAJAN

National Institute of Nutrition, Indian Council of Medical Research, Jamai Osmania,  
Hyderabad 500007

#### ABSTRACT

The seeds of *Indigofera glandulosa*, a wild legume grown in some parts of Deccan region, have been analysed for nutrient composition and amino acid profile. The legume contains 26% protein and is a good source of minerals and B-complex vitamins. Aminogram and bioassay for acute toxicity reveal that the seeds do not contain undesirable constituents. The possibilities of exploiting such innocuous wild legumes with good nutritive potential for edible purposes have been discussed.

**I**NDIGOFEA GLANDULOSA, commonly known as barbada, malmandi or befri is an annual herb found in parts of U.P., Bihar, Gujarat and the Deccan plateau. It has been described as nutritious and is believed to possess the qualities

of a tonic in Indian medicine<sup>1,2</sup>. Seeds of this wild legume are reported to contain 31% protein and cultivated varieties appear to contain even higher amounts<sup>3</sup> (37%). However, complete information on the nutrient composition and the

essential amino acid profile of this legume is not available. In view of the reported good qualities of this legume, it was of interest to investigate in

## RESULTS

The data on the nutrient composition are indicated in Tables I and II.

\* Data on the basis of present investigation.

Data on other pulses drawn from *Nutritive Value of Indian Foods*.<sup>9</sup>

detail the nutrient composition, the essential amino acid content and also to examine the possible presence of unusual toxic amino acids.

## MATERIALS AND METHODS

Sample of seeds of *Indigofera glandulosa* was obtained by the courtesy of the Department of Extension of the Ministry of Agriculture, Southern Region, Bangalore.

Proximate principles were determined by standard techniques<sup>4</sup>. Mineral and trace element composition were determined by methods described by Sandel<sup>5</sup>. The B-complex vitamins were estimated by fluorometric or microbiological methods<sup>4</sup>. Essential amino acids were assayed by both microbiological assays and by the use of automatic amino acid analyser, using appropriately processed protein hydrolysates of the sample<sup>6</sup>. Free amino acids were examined by two-dimensional paper chromatographic method using extractives of 70% alcohol, using butanol: acetic acid: water (12: 3: 5) and phenol: water (4: 1) with  $\text{NH}_4\text{OH}$  as described by Ivor Smith<sup>7</sup>.

Acute toxicity studies on extracts from 70% alcohol extract were carried out on day-old chicks by intraperitoneal administration of appropriate dosages of the extract concentrates<sup>8</sup>.

It can be seen from the results that malmandi is a good source of protein. The protein, however, is deficient in methionine and in tryptophan. Like other legumes, it is a good source of lysine. Arginine content in the seed protein is very high, being threefold higher than the levels seen in other legumes. In regard to the mineral composition, it compares favourably with the most of the commonly used pulses. It is a better source of iron and B-complex vitamins. The amino acid profile determined by both the automatic amino acid analyser and the two-dimensional paper chromatography did not reveal the presence of any unusual amino acid.

Acute toxicity studies by daily intraperitoneal administration of concentrates of 70% alcohol extracts to baby chicks for about a week did not indicate any demonstrable signs and symptoms of toxicity.

## DISCUSSION

The seeds of the wild legume, *Indigofera glandulosa*, are a good source of protein, minerals and vitamin B-complex. The quality of protein as measured by the amino acid profile compares favourably with other pulses which are commonly used. Since the crop is drought resistant and can be grown in dry

TABLE II

regions, it appears to be a good and low-cost source of nutritious food. Since it is a good source of B-complex vitamins, particularly niacin, consumption of this pulse, in combination with jowar, could control endemic pellagra seen among the low income groups.

The arginine content of this seed is unusually high. Several other hardy legumes such as *Lathyrus* and *Canavalia* species which are also drought resistant crops contain appreciable amounts of higher homologues of arginine<sup>12</sup>.

$\beta$ -Nitropropionic acid, a neurotoxic amino acid from *I. enneaphylla*<sup>13</sup> and indospicine, a hepatotoxic amino acid from *I. spicata*<sup>14</sup>, have been reported to restrict the utilisation of these species as food for cattle or human. Long term studies are now under progress to examine any possible untoward effects due to prolonged consumption of the seeds of *Indigofera glandulosa*.

## ACKNOWLEDGEMENTS

The authors are grateful to Dr. S. G. Srikanthia, Director, for his keen interest and to Miss Padmasini Asuri, Regional Home Economist (South), Bangalore, Ministry of Agriculture, Government of India, for providing the sample of seeds.

## LETTERS TO THE EDITOR

## HOLOGRAPHIC FORMATION OF EQUAL INCLINATION AND EQUAL THICKNESS FRINGES AND ESTIMATION OF REFRACTIVE INDEX OF SOLUTION

IN principle fringes of equal inclination can be formed if two parallel wavefronts, one lagging behind the other, are made to interfere and equal thickness fringes can be obtained when the interfering wavefronts are inclined to one another. Holographic interferometric method has been employed here to form them. While forming fringes of equal inclination, a cell with solutions of different concentration was placed in the path of the object beam to produce phase difference between the interfering wavefronts and thus an attempt has been made to compare refractive indices of solutions at different concentration.

A schematic diagram of the usual off-axis holographic experimental set-up is shown in Fig. 1. A 15 mw He-Ne laser is used as a source of coherent light. The laser beam is split into two by means of a beam-splitter. After expansion one beam directly goes on to the photographic plate and the other reaches the plate through the liquid cell. Polaroids are introduced in each beam to control their intensity ratio. The functions of the other optical components in the set-up are well known.

FIG. 1. Schematic diagram of the experimental set-up. L, Laser; M, Mirrors; S, Shutter; BS, Beam splitter; P, Polaroids BE, Beam Expanders; CL, Collimating Lens; LC, Liquid-Cell; H, Photographic Plate.

A double exposure hologram was made by giving the first exposure with the cell containing distilled water and the second exposure after replacing distilled water by a salt solution of known concentration. On reconstruction circular fringes have been observed. A set of similar holograms were made using solution of various concentrations and found that the number of fringes in each case

was proportional to the concentration of the solution. Figure 2 shows a typical system of circular fringes. In the second case the liquid cell is replaced with a plane parallel glass plate with a provision to measure its angle of rotation accurately. The first exposure was given when the plate was normal to the object beam and the second exposure after rotating the plate through a known angle. Reconstruction of the hologram has revealed a set of straight fringes which are shown in Fig. 3.

Fig. 2. Circular fringes for 10 gm of NaCl in 100 cc of distilled water.

FIG. 3. Straight fringes for 1.0° Tilt.

On the basis of the theory pertaining to the double exposure hologram the intensity distribution in the circular fringe system has been deduced to be

$$I = 2a^2 \left[ 1 + \cos \left( \frac{2\pi d}{\lambda} \cos \theta \right) \right]$$

where  $a$  is the amplitude of the object beam,  $d$  the path difference and  $\theta$  the angle of inclination with the axis. It is evident from this expression that the

fringes obtained in this case should be circular and are of equal inclination type.

Similarly, the intensity distribution in the case of straight fringes may be expressed by

$$I = 4a^2 \cos^2 \frac{\delta}{2}$$

where  $\delta$  is the phase difference. This equation clearly indicates that these fringes can be considered as fringes of equal thickness.

On the basis of a well known relation<sup>1</sup>  $\mu t \cos \theta = n\lambda$  we have established a relation between refractive indices of two solutions at different concentrations by making use of the circular fringes. If  $r$  and  $r'$  are respectively their refractive indices, their ratio is given by

$$\frac{\mu'^2}{\mu^2} = \frac{n_1^2 r_2^2 (r_1'^2 - r_1'^2) - n_2^2 r_1'^2 (r_2'^2 - r_2'^2)}{n_1^2 r_2'^2 (r_1'^2 - r_1'^2) - n_2^2 r_1'^2 (r_2'^2 - r_2'^2)}$$

In this formula  $r_1, r_2$  are the radii of  $n_1$ th ring and  $r_1', r_2'^2$  are the radii of  $n_2$ th ring in each case.

The following are the various values obtained for different variables of the above equation.

(1) For 20 gm of NaCl in 100 cc of distilled water

$$\begin{array}{ll} n_1 = 2 & n_2 = 5 \\ r_1 = 1.3 \text{ cm.} & r_1 = 3.0 \text{ cm.} \end{array}$$

(2) For 40 gm of NaCl in cc of distilled water

$$\begin{array}{ll} n_1 = 2 & n_2 = 5 \\ r_1' = 1.2 \text{ cm.} & r_2' = 2.8 \text{ cm.} \end{array}$$

On substituting these values in the above equation we get

$$\frac{\mu'}{\mu} = 1.085$$

This result appears to be in the order of the values expected as the value obtained with Jamin's interferometer is 1.078.

This method is applicable not only to the solutions of different concentrations but also to gases of different pressures and temperatures. The advantage of this method lies in its applicability to the dynamically varying situations using pulsed laser.

## ANNEALING CHARACTERISTICS OF INDUCED FISSION TRACKS IN MICACEOUS MINERALS

THE presence of uranium (even traces) in all the minerals is the basis of fission track technique used by Price *et al.*<sup>1</sup> for dating of mineral rocks and pegmatites<sup>2</sup>. Due to the effect of thermal annealing over the long periods of mineral history the ages determined by fossil fission track technique have been observed<sup>3</sup> to be lower than the corresponding ages determined by radiometric methods<sup>4,5</sup>. This work confines to the study of annealing effects observed at laboratory temperatures in micaceous minerals of Kodarma zone, Bihar mica belt.

There is no theory which can explain perfectly the annealing of radiation damage and rejuvenation of minerals on heating to various temperatures. However, some models have been proposed on the basis of experimental results<sup>6</sup>. According to one such model : when the mineral is heated to high temperatures the redistribution of atoms in the region affected by the ionising fission fragments takes place and any sort of strain present due to the radiation damage disappears. The degree of this annealing effect depends upon the temperature to which the sample is heated and the time of heating. For each mineral there is a characteristic high temperature at which the effect of strain is removed totally and the complete rejuvenation of it takes place. This temperature is known as annealing temperature.

The results of high temperature annealing experiments<sup>7</sup> in synthetic mica have shown that tracks formed nucleation sites for the decomposition of this material. On heating, the portion of the tracks in the interior of the crystals became narrower and eventually disappear.

It is clear from this discussion that the possibility of annealing of radiation damage and of track fading in minerals always exists. The track fading can be caused by a short time, high temperature event or by a long time anneal at a slightly elevated temperature during the geothermal history of earth's crust.

The minerals selected for annealing study are muscovite and biotite samples collected from Kodarma zone of Bihar mica belt. The age of the minerals has been estimated in a previous study<sup>2,3</sup>.

The range of each fossil fission track was determined by recording its projection along a calibrated microscope scale and dip in the sample by a fine motion Z screw of a Leitz binocular microscope using a magnification of 600 $\times$ . More than 500 tracks were measured in each sample. The mean range of fission tracks has been observed to be 18.5  $\mu$  and 15  $\mu$  in muscovite and biotite, respectively.

1. Robert, W. Wood, *Physical Optics*, The Macmillan Company, 1959.

The procedure adopted for the experimental study of annealing effects is the same as reported by Mehta and Rama<sup>8</sup>. It has been observed that the track length and the density of tracks remain unaltered at 100°C and 200°C in both the samples. Prolonged heating at 300°C reduces the track length slightly (18.2  $\mu$ ) in muscovite but the effect is quite appreciable in case of biotite (13.5  $\mu$ ). At 400°C, the track fading is more intense but at 500°C the tracks completely fade out in biotite samples for prolonged heating (6 hours) while in case of muscovite samples their density is reduced by 10%. On further heating of muscovite samples to 700°C it has been found that cylindrical tracks fade out into small distorted circular etch pits. This stage corresponds to nucleation phase change in mica<sup>7</sup>.

It was originally thought by Price *et al.*<sup>9</sup> that the fading of tracks during observation in the electron microscope was due simply to the warming of the samples by the electron beam. However, tracks in synthetic mica showed no fading in the microscope. Laboratory experiments have been done by various groups<sup>10-12</sup> to determine the annealing temperatures of various minerals to unravel the geothermal history of earth's crust. Our results are summarized as follows:

(1) Both muscovite and biotite samples remain unaffected at low temperatures and the reduction in track density is so small that the age correction may be neglected.

(2) The annealing temperature for muscovite is 700°C and for biotite it is 500°C. Thus our result is in agreement with that reported by Mehta and Rama<sup>8</sup>.

(3) The small difference observed in average fossil track length and the induced track length in micaceous minerals indicates that there has been no major orogenic metamorphic cycle in the geothermal history of the region from where the samples were collected.

## PARAQUAT-CALCIUM ADSORPTION EQUILIBRIUM IN SOIL CLAYS

PARAQUAT (1 : 1'-dimethyl-4 : 4'-dipyridylum dichloride) a divalent organic cation, a weedicide and a defoliant, is quickly deactivated due to strong adsorption on soil colloids. Not all the adsorbed paraquat is converted to the herbicidally inactive form but a portion goes into the non-exchangeable form and loses its bio-activity<sup>1</sup>. As a cation, this herbicide is known to get preferentially adsorbed on soils, in preference to ammonium<sup>2</sup>. However, in the soil,  $\text{NH}_4^+$  is only a minor exchangeable ion, but it is  $\text{Ca}^{2+}$  which forms a major portion of the exchangeable cations in many soils. The adsorption behaviour of paraquat<sup>2+</sup> in the presence of  $\text{Ca}^{2+}$  is not known. In order to find out the presence of these two ions on clays, paraquat<sup>2+</sup> -  $\text{Ca}^{2+}$  equilibrium studies were carried out on clay fractions isolated from red, laterite, black and *karl* soils, following the methods of Vansant and Uytterhoeven<sup>3</sup>. Mineralogically red and laterite soil clays are dominantly kaolinitic and black and *karl* soil clays are dominantly montmorillonitic. Paraquat<sup>2+</sup> was determined by alkaline dithionite method<sup>4</sup> and  $\text{Ca}^{2+}$  by titrating against standard versenate.

The results reveal that larger quantities of  $\text{Ca}^{2+}$  are adsorbed on kaolinite-dominant clays than on montmorillonite-dominant clays, while paraquat<sup>2+</sup> is preferentially adsorbed on montmorillonitic clays. It is expected that in the expanding montmorillonitic clays, the organic cation is fixed, in between the clay unit cells in a non-exchangeable form, unlike in the non-expanding kaolinitic clays. The size of paraquat ion has been shown to be almost the same as the inter-layer space of montmorillonite<sup>2</sup>, which facilitates the specific adsorption of the cation in such clays.

This is further confirmed by the values of  $\Delta G$  (adsorption) obtained from the equilibrium values of the reaction  $\text{paraquat}^{2+} \rightarrow \text{Ca}^{2+}$ . These values were calculated from the concentrations of  $\text{Ca}^{2+}$  and paraquat<sup>2+</sup> in the equilibrium solution and the quantities of these ions adsorbed on the clays as per the method of Vansant and Uytterhoeven<sup>3</sup>. On red and laterite soil clays the  $\Delta G$  values are

+953.8 cal/equiv. and +798.9 cal/equiv. respectively, whereas those on the black and *karl* soils the  $\Delta G$  values are -53.7 cal/equiv. and -59.6 cal/equiv. respectively. These indicate the preference of  $\text{Ca}^{2+}$  on red and laterite soils and paraquat<sup>2+</sup> on black and *karl* soils. Hence, deactivation of the weedicide is higher in black and *karl* soils than in red and laterite soils.

#### PRIMORDIAL NUCLEAR MATTER AND NUCLEOSYNTHESIS

MANY theories have been proposed to explain the observed relative abundance of elements in the universe particularly in the solar system where experimental data are easily available. None of these theories is in a position to explain all the features of the abundance curve<sup>1</sup>. The latest approach made by Burbidge *et al.*<sup>2</sup> introduces eight different processes to create elements to cover the entire mass region (1 to 260). The fundamental question about the starting material however remains to be settled. The failure of  $\alpha, \beta, \gamma$  theory which assumes neutrons as the primordial matter lead Burbidge *et al.* to assume that hydrogen was the starting material. In this note it is shown that neutron is a better choice and elements can be synthesized from neutron matter. More detailed results will appear elsewhere.

The well-known fact that our observable universe is made up of neutrons, protons and electrons leaves us with only two choices: neutron and hydrogen. A convincing proof about the neutron being the primordial matter comes from beta decay. In beta decay a neutron decays to proton an electron and a neutrino. It has been experimentally proved that the properties of beta particles emitted from a nucleus and those of the extranuclear electrons are same (same charge, mass, spin, etc.). This strongly suggests that they have the same origin. In other words electrons are merely the decay products of neutrons. If this is true, then neutrons must have existed in the prestellar conditions and must be taken as the primordial matter.

The decay of neutrons can be represented as

the decay energy of neutrons will raise the temperature of the mixture ( $n + p + e + \nu$ ) to a billion degree or more. When the proton density becomes high the reverse reaction  $n \leftarrow p + e + \nu$  will stop the neutrons from being destroyed. At this temperature fusion reactions will start to build up the heavy nuclei. Neutron capture will be another competing reaction which will contribute to element formation.

The hydrogen will be the product of a later stage when under suitable conditions protons and electrons combine to form a bound system.

#### A REINVESTIGATION OF IRON-RESACETOPHENONEOXIME COMPLEX : AN IMPROVED PROCEDURE FOR THE SPECTROPHOTOMETRIC DETERMINATION OF IRON (III)

IN our attempts to determine the stability constant of the iron-resacetophenoneoxime complex, we observed that iron (III) and resacetophenoneoxime give rise to a mixture of complexes in addition to the single species of 1:1 complex (pH 4.5 to 7.0) reported by Raja Reddy *et al.*<sup>1</sup>. They made use of the Hilger Spekker Absorptiometer with Ilford colour filters in their investigations. We have now made a detailed study using UVISPEK Photoelectric Spectrophotometer (Hilger and Watts Ltd., manual type).

The reagent has negligible absorbance in the spectral region studied, 400 to 650 nm. The absorption curves were drawn at different pH values; the measurements were made against the reagent blank in 10% v/v aqueous ethanol. The metal to reagent ratio was maintained at 1:50 because it was found that at lower concentrations such as 1:6 turbidity developed thereby causing difficulties for accurate measurements.

An isobestic point in the pH range 6.0 to 8.3 at 580 nm clearly indicated the presence of mixture of complexes. But in the pH range 2.5 to 5.0, the absorption curves do not pass through the isobestic point indicating the presence of a single species which is in confirmation with the results reported by Raja Reddy *et al.* at pH 4.5. At pH

values between 2.0 to 3.0 the colour of the complex is violet and fades away with time, while at higher pH values the colour is reddish-violet and stable for 24 hrs.

In view of these facts it is not possible to determine the stability constants by the Job's method of continuous variation. These studies, however, have revealed that there is no need at all for maintaining rigorous control of pH for the determination of Fe(III) when the measurements of the optical densities are made at 580 nm. We, therefore, recommend the following modified procedure for the determination of iron(III) with resacetophenoneoxime in 10% v/v ethanol-water medium.

An aliquot of iron(III) solution is treated with resacetophenoneoxime in ethanol in fiftyfold excess and the pH adjusted to 6.0 to 8.3 with dilute sodium hydroxide (0.01 M) and the absorbance measured at 580 nm. Beer's law is obeyed in the range 1-14 ppm.  $\text{Na}^+$ ,  $\text{K}^+$ ,  $\text{NH}_4^+$ ,  $\text{Hg}^{++}$ ,  $\text{Cd}^{++}$ ,  $\text{Ca}^{++}$ ,  $\text{Mg}^{++}$ ,  $\text{Zn}^{++}$ ,  $\text{Cl}^-$ ,  $\text{Br}^-$ ,  $\text{I}^-$ ,  $\text{NO}_3^-$ ,  $\text{SO}_4^{--}$  have no effect even when present in excess.  $\text{CH}_3\text{COO}^-$ ,  $\text{F}^-$ , and  $\text{Al}^{+++}$  are tolerable upto 50 ppm. Oxalate, citrate, borate and  $\text{Mn}^{++}$  interfere when the concentration exceeds 10 ppm. The tolerance of a given ion is a maximum amount that can produce an absorption difference of 3% from that of the iron complex (Fe: 5 ppm). Phosphate, carbonate and  $\text{Co}^{++}$  interfere seriously. Copper<sup>2+</sup>, nickel<sup>3</sup> and palladium<sup>1</sup> interfere as they produce precipitates with the reagent.

### INFRA-RED CARBONYL FREQUENCIES OF HYDROXY CHALKONES AND CHROMONES

IN some of our earlier papers<sup>1-3</sup> on the effect of conjugation and hydrogen bonding on the infra-red carbonyl frequency, certain abnormal features were observed. There were special cases in which the introduction of a hydroxyl group, in a position that can cause chelation, raises unexpectedly the infra-red carbonyl frequency rather than lower it. This was attributed to the presence of a conjugated

—O—C=C—C=O system in which the ethylenic double bond was not a part of a benzenoid ring. Such an abnormal feature was first noticed by

comparing the infra-red spectra of 5-hydroxy-flavones and isoflavones on the one hand and the corresponding flavanone and isoflavanone derivatives on the other<sup>4-5</sup>. The former group of compounds shows this special effect whereas the latter group does not, obviously due to the absence of an ethylenic double bond in the oxygen ring. That the benzenoid double bond is not capable of bringing about such an effect, was established by the recent study of the I.R. spectra of suitably substituted hydroxy xanthenes, benzophenones and anthraquinones<sup>6</sup>.

In a further study discussed in this paper, we have examined compounds which have an ethylenic double bond but without oxygen linked to it, *i.e.*, chalkones (I). In them, the chelation of the ortho hydroxyl with the chalkone carbonyl brings about the normal lowering of the C=O frequency. When the chelation is removed by acetylation or methylation, the C=O frequency is increased. Thus 2'-hydroxy-4',6',4-trimethoxy chalkone absorbs at 1613  $\text{cm}^{-1}$ , while 2',4',6',4-tetramethoxy chalkone absorbs at 1648  $\text{cm}^{-1}$  and 2'-acetoxy-4',6',4-trimethoxy chalkone absorbs at 1652  $\text{cm}^{-1}$ . The same is the case with other chalkones (Table I). Thus chalkones behave similar to flavanones and isoflavanones as against flavones and isoflavones obviously due to the absence of ether oxygen as the electron source.

TABLE II

Infra-red carbonyl frequencies of chromones (II)

| Chromone                                 | $\nu_{\text{max}}^{\text{KBr}} (\text{C}=\text{O}) \text{ cm}^{-1}$ |
|--|---|
| 1. 5, 7-dihydroxy-2-methyl chromone      | 1660  |
| 2. 5, 7-diacetoxy-2-methyl chromone      | 1648  |
| 3. 5-hydroxy-7-methoxy-2-methyl chromone | 1658  |
| 4. 5-acetoxy-7-methoxy-2-methyl chromone | 1645  |

As representing a simpler structure analogous to flavones and isoflavones, a few chromones have been studied for their infra-red carbonyl frequency with and without chelation (Table II); here also, as expected, chelation brings about the special effect, i.e., the carbonyl frequency is increased when chelation is present. Hence the generalization regarding this unusual chelation effect has been further supported.

### SYNTHESIS OF DERIVATIVES OF SOME NATURALLY OCCURRING CHALCONES

THE synthesis of the methyl ether of dihydro 'Bavachalcone', a naturally occurring chalcone isolated from the seeds of *Psoralea corylifolia* Linn.<sup>1</sup> and some chalcones allied to the chalcone 'Flemichapparin' isolated from *Flemingia chappar* Ham<sup>2</sup> have been described here.

4-Isoamylresorcinol<sup>3</sup> was synthesised by the Nencki reaction by heating resorcinol with isovaleric acid in presence of anhydrous zinc chloride.

A Clemmensen reduction of the above ketone afforded 4-isoamylresorcinol<sup>4</sup>. A second Nencki reaction on the latter with acetic acid and anhydrous zinc chloride yielded 2, 4-dihydroxy-5-isoamylacetophenone as an oil (2, 4-DNP, m.p. 200°) which was partially methylated with methyl iodide in acetone solution to give 2-hydroxy-5-isoamyl-4-methoxyacetophenone as a colourless oil (2, 4-DNP, m.p. 206°). The latter when condensed with *p*-anisaldehyde gave orange-red plates of the methyl ether of dihydrobavachalcone (I) crystallised from dilute alcohol, m.p. 88–89° (Calcd. for  $\text{C}_{22}\text{H}_{26}\text{O}_4$ : C, 71.5; H, 7.3; Found: C, 71.1; H, 6.9%).

$\nu_{\text{max}}^{\text{CH}_2\text{Cl}_2}$  1630 (–CO–CH=CH–),  
2850 (–OCH<sub>3</sub>)  $\text{cm}^{-1}$ .

The synthetic route employed for the synthesis of chalcones allied to Flemichapparin is similar to that described by the earlier workers<sup>2</sup>. It however differs in the method of methylation and debenzoylation of the methylated product.

Resacetophenone-4-benzylether<sup>5</sup> on oxidation with potassium persulphate gave 4-benzoyloxy-2, 5-dihydroxyacetophenone, m.p. 158–61° (2, 4-DNP, m.p. 240–42°). Methylation of the latter with dimethyl sulphate in acetone solution was attempted but working out as usual and crystallization from ligroin afforded only 4-benzoyloxy-2, 5-dimethoxyacetophenone, m.p. 110–11° (2, 4-DNP, m.p. 176°). However, methylation with dimethylsulphate and NaOH yielded the 5-methyl ether, m.p. 128–29° (2, 4-DNP, m.p. 236–38°). The latter on debenzoylation with hydrochloric acid in acetic acid produced 2, 4-dihydroxy-5-methoxyacetophenone, m.p. 169–71° (2, 4 DNP, m.p. 288–9°). The debenzoylated compound on condensation with different aldehydes gave Flemichapparin IIa (identified by m.m.p. and superimposable IR) and the chalcones related to it having the formulae II b–II d.

# INVERSE RELATIONSHIP BETWEEN PLASMATOCYTES AND ADIPOHAEMOCYTES OF *DYSDERCUS CINGULATUS* FABR. (HEMIPTERA : PYRRHOCORIDAE) RELATED TO AGE AND REPRODUCTIVE CYCLES

THE changes in the percentage of one or the other types of haemocytes during their life cycle in *Forficula auricularia*<sup>1</sup>, *Prodenia eridania*<sup>2</sup>, *Ephesia kühniella*<sup>3</sup>, *Rhodnius prolixus*<sup>4</sup>, *Galleria mellonella*<sup>5</sup> and *Drosophila euronotus*<sup>6</sup> have been recorded. The present information on *Dysdercus cingulatus* is related to the changes in the percentage of plasmatocytes and adipohaemocytes related to age and reproductive cycles of the adults.

The method for differential counts of these cells is based on that of Jones<sup>4</sup> with slight modification for counting various haemocytes under light microscope. For this purpose the blood smears were stained with Giemsa's stain. The confirmation of adipohaemocytes (haemocytes with fat droplets) was also made by using Sudan Black-B stain.

It was recorded that in both sexes of the newly emerged *D. cingulatus*, the percentage of adipohaemocytes is much higher than that of the plasmatocytes; and males have significantly higher percentage of adipohaemocytes than the females. The percentage of plasmatocytes in the newly emerged adults is higher in females than in the males (Fig. 1, A and B). Thereafter, in both sexes, the plasmatocytes increase in number. Following the emergence in contrast to the percentage of plasmatocytes, that of adipohaemocytes generally decreases with respect to advancing age of both sexes (Fig. 1, B). However, in males, the initial decrease in the number

Fig. 1. A, Plasmatocytes, B, Adipohaemocytes.  
o—o—o—o—o Male  
o—o—o—o—o Female

of adipohaemocytes is more pronounced than in the females. In *D. cingulatus* at  $29^\circ\text{C} \pm 1^\circ\text{C}$  and 70%-80% R.H., the first batch of eggs is laid on 6th or 7th post-emergent day and then the second batch is oviposited on 10th or 11th day. Therefore, it is clear that the increase in the percentage of plasmatocytes and the decrease of the adipohaemocytes are quite significant before the first

reproductive cycle. Changes in the percentage of both types are slow and less marked.

From the present data on *D. cingulatus*, it is concluded that there is a distinct sexual difference in the population of plasmotocytes and adipohaemocytes which is not known in any insect species so far studied. Further, the latter type of haemocytes either degenerate or get consumed during the growth and metabolism of adults whereas, the former cells are produced in larger numbers. Such an inverse relationship between the plasmotocytes and adipohaemocytes has not been reported in any hemimetabolous insect. However, during the short adult life of *Ephestia kuehniella*<sup>3</sup> it is reported that plasmotocytes increase and spheroidocytes (loaded with fat globules) decrease.

#### DIURNAL VARIATIONS IN ACETYLCHOLINE- ESTERASE ACTIVITY IN THE NERVOUS SYSTEM OF THE AESTIVATING SNAIL, *PILA GLOBOSA*

DESPITE the different types of rhythms reported in molluscs<sup>1</sup>, no work was done on the rhythms in enzyme activities. The snails are known to be active during nights<sup>2</sup>, and hence there might be variations in nervous activity in terms of acetylcholinesterase (AChE) activity during different periods of the day. The prosobranch snail *Pila globosa* aestivates during summer<sup>3</sup>. Since this dormancy involves several physiological changes on the part of the snail<sup>4</sup>, it would be interesting to study the diurnal variations in the AChE activity in the nervous system of normal, aestivated and revived snails, and also with reference to the effect of eserine, a known inhibitor of AChE<sup>5</sup>.

Normal snails were maintained in tap water in aquarium jars and fed with *Hydrilla*. Aestivation was induced in them by burying in dry sand in wooden boxes. Aestivated ones were revived by placing them in water in glass jars, and they were soon fed with *Hydrilla* and used one day after revival for experimentation.

For the assay of AChE activity, the nervous tissue, including the ganglia, connectives and com-

missures was isolated in cold from normal, aestivated and revived specimens separately. Six different timings, viz., 12 noon, 4 p.m., 8 p.m., 0 hrs, 4 a.m. and 8 a.m. were chosen to cover the 24-hour period of the day. Each time six samples were analysed. The experiment was repeated for three consecutive days to see whether the pattern of activity remained the same on all the three days. 5% (W/V) homogenates of the nervous tissue were prepared in 0.25 M sucrose solution. The homogenates were assayed for AChE activity, adopting the method of Metcalf (1951) as given by Glick (1957)<sup>6</sup> with due modifications to suit the present material. The enzyme activity was expressed as  $\mu$  moles of ACh hydrolysed/mg protein/hr.

For studying the effects of eserine, the incubation mixtures received 0.1  $\mu$  mole of eserine.

The results clearly show that a regular diurnal rhythm of AChE activity exists in the nervous system of *Pila globosa* (Fig. 1). An interesting

FIG. 1. AChE activity levels at different periods of the day in the nervous system of normal, aestivated and revived *Pila globosa*.

feature was that this rhythm was observed in the aestivated and revived specimens also, indicating that this is an endogenous activity and was not disturbed during aestivation. The activity was found to be maximum at 4 p.m. and thereafter it decreased gradually, reaching the minimum at 12 noon in all the specimens studied. A decrease in the enzyme activity was observed at all periods in the aestivated specimens as compared to the normals. Upon revival, the activity tended to recover towards the normal level (Fig. 1).

*Helix*, *Limax* and other snails have been reported to become active towards the night<sup>2</sup>; and thus a higher level of nervous activity could be expected during night time. Since AChE activity represents one of the several facets of neuronal activity, the

observed rhythm in AChE activity in the present investigation can be presumed to go hand in hand with the general state of activity of the animal. Cholinesterase activity rhythm of slightly different nature has been shown in the slug *Vaginulus*<sup>7</sup> wherein the maximum activity was at 4 p.m. and minimum activity at 0 hrs, and in the scorpion *Heterometrus*<sup>8</sup> wherein the maximum and minimum activities were at 4 p.m. and 4 a.m. respectively.

Murali Mohan and Muralikrishna Dass (1969)<sup>9</sup> reported a decrease in AChE activity of the nervous system during aestivation of *Pila globosa*. In the present study, while maintaining the rhythm of AChE activity as in the normal snail, the aestivated snail showed a general decrease in the AChE activity at all the periods of the day in comparison to the normal snails. This indicates that the decrease in AChE activity is explicit during aestivation in the nervous system of the snail.

Eserine inhibited the AChE activity at all periods in normal, aestivated and revived snails, with the inhibition being greater in lower activity periods and *vice versa* (Fig. 2). This shows that the snail

FIG. 2. Per cent inhibition of AChE by eserine at different periods of the day in the nervous system of normal, aestivated and revived *Pila globosa*.

is able to overcome the inhibitory effect to a large extent during the periods of higher activity. It may be hypothesized that the enzyme is subjected to masking and unmasking effects during low and high activity periods respectively, resulting in respective inhibition and activation during those periods. These possible masking and unmasking interactions might accordingly facilitate or antagonize the inhibitory influence of the effector added.

The authors thank Prof. K. S. Swami for his help. This work was supported in part by a grant (FG-In-395, Project A7-ADP-31) made by the United States Department of Agriculture under P.L. 480.

#### BLOOD VESSELS AND CAPILLARIES OF NORMAL AND LEUCODERMIC SKINS

In the melanocytes of the normally pigmented skin, the enzyme tyrosinase/dopa oxidase converts dopa to melanin. For the activity of this enzyme molecular oxygen is necessary<sup>1</sup>. Molecular oxygen reaches these melanocytes through haemoglobin *via* blood. Therefore the blood vessels and capillaries of the skin are of vital importance for normal skin pigmentation<sup>2</sup>. According to Becker<sup>3</sup>, many authors believe that in vitiligo/leucoderma an impairment in vascularity of the skin is present. We have therefore investigated the blood supply system of the normal and leucodermic skins.

Leucodermic and the corresponding normal human skin were obtained by punch biopsy (4 mm) after local anaesthesia. They were blotted free of blood and 10  $\mu$  sections were cut on a freezing microtome. These sections were then stained for alkaline phosphatase activity<sup>4</sup>, which selectively stains the blood vessels and capillaries in the skin<sup>5</sup>.

All the major blood vessels and capillaries could be identified in both the normal and leucodermic skins (Figs. 1-4). Since the alkaline phosphatase activity was normal, leucodermic skin does not represent traumatized skin<sup>5</sup>.

We<sup>6</sup> have recently shown that leucodermic skin can peroxidatively convert tyrosine to dopa, but is incapable of converting dopa to melanin *via* tyrosinase. As mentioned earlier molecular oxygen is necessary for this conversion. Since the blood supply and consequently oxygen supply to leucodermic skin is normal (Figs. 1-4) the cause for amelanogenesis lies elsewhere. It would be either due to the absence of the enzyme tyrosinase in leucodermic skin as it is undetectable by histochemical methods<sup>7</sup>, or it could be due to the presence of some antioxidant in the melanocytes which competes with tyrosinase for oxygen. One such antioxidant widely used in industry, viz., monobenzylether of hydroquinone has been identi-

fied by Oliver *et al.*<sup>8</sup> as the cause in certain types of occupational leucoderma.

The research grants from Indian National Science Academy and from Shri Ashabhai Patel Trust are gratefully acknowledged.

# DISTRIBUTION AND ABUNDANCE OF THE PLANKTONIC SHRIMP, LUCIFER, IN THE NEARSHORE WATERS OFF VISAKHAPATNAM (BAY OF BENGAL)

The planktonic shrimp belonging to the genus *Lucifer* is a very common constituent of the zooplankton in the seas around India. Three species, *L. penicillifer*, *L. hanseini* and *L. typus* occur in the nearshore waters off Visakhapatnam, of which *L. penicillifer* contributes to the bulk of the lucifers. The present paper reports the seasonal abundance and distribution of the lucifers in relation to the prevailing hydrographical conditions.

Samples of zooplankton were collected from March 1968 to February 1970 with an International Coarse Silk Net (mesh size 0.28 mm) by vertical hauls from a depth of 40 metres. The developmental stages of all the three species were enumerated together, owing to the absence of well marked features differentiating them, while the adults were sorted out species-wise, and counted separately.

The protozoa showed a major peak in June and two minor peaks, one in April and another in December, 1968. During 1969 the major peak was in September, and two minor peaks, one in March and the other in December. The peaks of the juveniles more or less followed the same pattern as the protozoa, during both the years. The adults were present practically throughout the year. Numerically they were smaller than the developmental stages but at no time totally absent except in June 1969. The protozoa ranged from 0.02% to 3.13% of the total zooplankton in March and June 1968; the juveniles from 0.03% to 2.04% in April and October 1968 and the adults from 0.01% to 0.64% in April and October 1968. Numerically the protozoa were at their maximum (35 m<sup>3</sup>) in June 1968 and minimum (0.37/m<sup>3</sup>) in July 1968; the juveniles at their maximum (26.59 m<sup>3</sup>) in March 1969 and minimum (0.16/m<sup>3</sup>) in January 1970 and the adults at their maximum (2.81 m<sup>3</sup>) in November 1969 and minimum (0.16/m<sup>3</sup>) in August 1968. The major peaks of the developmental stages were observed in relatively high saline waters of the Northerly Current (February-June) and minor peaks during the low saline Southerly Current period (October-December). No appreciable difference in the numerical abundance of the adults was observed during the two current periods. It would also appear that there are at least 4-5 broods in a year.

Of the three species, *L. penicillifer* was the most common and the dominant species. *L. hanseini* appeared in smaller numbers throughout the period

of investigation. *L. penicillifer* is a well-known inhabitant of the coastal waters in the Indo-Pacific region. *L. typus* appeared in the coastal waters in large numbers from February to June during the Northerly Current period along with the incursion of the oceanic waters into the coastal region. The preliminary observations we have made from samples collected during a cruise (April-May 1969) to the Andaman Islands, Bay of Bengal (Visakhapatnam to Port Blair via Madras) also revealed the same pattern of distribution. *L. penicillifer* was abundantly present in the samples collected within 100 km distance from the coast. Large numbers of *L. typus* were present in waters beyond the 100 km zone. The pattern of distribution of the three species clearly shows that *L. typus* is a true oceanic species, which occasionally appears in the nearshore region along with the incursion of the offshore and oceanic waters into the coastal region during the Northerly Current period. Wickstead<sup>1</sup> and Bowman and McCain<sup>2</sup> also observed *L. typus* as an oceanic species in the Singapore Strait and Western North Atlantic respectively. *L. typus* is thus a good practical indicator of offshore and oceanic waters incursion into the nearshore region off Visakhapatnam.

One of us (K. V. R.) thank the C.S.I.R. for the grant of a Research Fellowship during the tenure of which the present work was undertaken. We also thank Professor K. Hanumantha Rao, Head of the Department of Zoology, for providing all facilities and encouragement.

## A NEW SPECIES OF SPIDER OF THE GENUS *PEUCETIA* THORELL (FAMILY OXYOPIDAE) FROM ORISSA, INDIA

THE genus *Peucetia* Thorell of the family Oxyopidae appears to be little known from India. The first species was described from India by Stoliczka (1869) and subsequently Pocock (1900) described three species. Recently Tikader (1965, 1970) has described two species of the genus *peucetia* from India. While examining the spider collection from Orissa (India) the following new species was noticed. The type specimen has been deposited in the Zoological Survey of India, Calcutta.

The author's sincere thanks are due to the Director, Zoological Survey of India, for giving

necessary facilities and to Dr. J. K. Sen for encouragement for this work. He is indebted to Dr. B. K. Tikader, Deputy Director, Zoological Survey of India, Western Regional Station, Poona, for guidance and verification of his identification and help in the preparation of this paper.

*Peuceetia harishankarensis* Sp. Nov.

**General:** Cephalothorax light green, legs reddish brown, abdomen magenta colour. Total length 17.00 mm. Carapace 6.00 mm long, 4.50 mm wide; abdomen 11.00 mm long, 5.55 mm wide.

FIG. 1. A-B. *Peuceetia harishankarensis* sp. nov. A, Dorsal view of female, legs omitted; B, Epigyne.

**Cephalothorax:** Longer than wide, narrow in front and provided with conspicuous black spots and U-shaped red marking. Cephalic region high. Eyes eight and situated on the elevated portion of the cephalic region and all eyes encircled by black patch. Posterior row slightly procurved and equidistant, anterior row recurved and anterior medians very small. Clypeus long and broad provided with a pair of black lines extending from ocular area to the base of the fang. Sternum oval; clothed with fine hairs. Legs long and strong with conspicuous long spines.

**Abdomen:** Long, narrowing behind, clothed with hairs. Middorsally provided with a longitudinal

broad olive green band extending from base to the end of abdomen, as in Fig. 1. Ventral side light colour. Epigyne as in Fig. 1B.

**Type Specimen:** One female in spirit (HOLOTYPE).

**Type-locality:** Gandhamardan Hill (3,090 feet) near Harishankar, Bolangir, Orissa, India. Coll. Dr. J. K. Sen. 3-11-1973.

This species resembles *Peuceetia viridans* (Heritz.) but differs as follows: (i) Cephalothorax with black spots but in *P. viridans* cephalothorax without black spots. (ii) Epigyne also structurally different.

# A NEW REPORT ON WHITE FLOWERS IN *TEPHROSIA PURPUREA* PERS. COMPLEX

*Tephrosia purpurea* is reported to be polymorphic species as observed in the populations growing at Waltair<sup>1</sup>. This feature is also shown in populations of this species in most other countries in which it occurs. The same is true for *T. purpurea* at Jodhpur. Two populations: (1) procumbent showing *gigas* vegetative features; and (2) erect with smaller-sized vegetative parts and pods have been noted<sup>1</sup>.

As far as the information of the author goes, this is the first report of *T. purpurea* having pure white flowers. The colours of flower in populations range from crimson-red, red, pink, light pink, pinkish-white and pure white. The occurrence of plants having white flowers was first observed by the author in 1973 but their number appeared to increase in 1974. However, the white colour of petals still remains very rare. After measurements of different vegetative and floral characters of pink and white flowered plants, no distinctive differences were found. The major distinction was observed in pollen grains. The pollen grains when mature were found distinctly triangular in pink-flowered stamens (Fig. 1); whereas those in white-flowered ones, they were just circular (Fig. 2). However, the distinct red-coloured flowers sometimes possessed some roundish pollen grains as well. There appears to be some distinct difference of pollen grains and seed coat colours and their mottling in populations of *T. purpurea*.

Ramanathan<sup>2</sup> reported a chromosome number of  $2n=24$ ; whereas Tandon and Malik<sup>3</sup> observed  $n=11$  in *T. purpurea*. The latter number is confirmed by Venkateswarlu and Rao<sup>4</sup> for this species. Naturally occurring allotetraploid races have already been reported<sup>2,4</sup>.

FIGS. 1-2. Triangular pollen grains in pink-flowered plants of *T. purpurea*,  $\times 1,280$ . Fig. 2. Circular pollen grains in white-flowered plants of *T. purpurea*,  $\times 1,280$ .

This discovery of white coloured flowers in *T. purpurea* complex is noteworthy and its cytological study might reveal interesting results in its populations.

Thanks are due to Prof. Dr. H. C. Arya for facilities and to Shri L. N. Harsh for assistance given in the present study. Financial assistance received from PL-480 Project is also acknowledged.

#### EFFECT OF DIFFERENT NUTRIENT MEDIA ON THE GROWTH AND SPORULATION OF *USTILAGINOIDEA VIRENS* (CKE) TAKAHASHI

*Ustilaginoidea virens* causing false smut of rice was first reported from Tinnevely in Tamil Nadu State by Cooke<sup>1</sup>. Since then it has been reported from various parts of the world like Japan, U.S.A., etc. In the year 1973, it appeared in an epidemic

form in some areas at Jabalpur. The disease being of considerable economic importance, it was necessary to carry out certain physiological studies on the fungus.

The present paper deals with the effect of different nutrient media. The development of a suitable medium for growth and sporulation would facilitate studies of factors affecting the formation of metabolites in pure culture. From a practical standpoint, a medium capable of stimulating sporulation (conidial) of the fungus would aid in the preparation of spore suspensions required for inoculation of large populations in disease resistance breeding programs and in studies on the nature of disease resistance. Pure culture of *U. virens* was obtained by the following method.

Fresh sclerotia of false smut of rice (Fig. 1) collected from the field during 1973-74 crop from

FIG. 1. False smut of Rice: Infected earhead.

Agricultural Experimental fields, Adhartal, Jabalpur, were used for the present study. For obtaining axenic culture a sterilized coverslip was put in the centre of a petridish containing yeast-peptone-potato-dextrose-agar medium (YPPDA yeast 100 mg; peptone

TABLE I

*Dry weight, colony character and sclerotial formation of U. virens on different nutrient media (after 45 days of incubation at 23° C)*

| Medium                        |    | Dry weight (mg) | Colony color           | Sclerotial formation with conidia |
|-------------------------------|----|-----------------|------------------------|-----------------------------------|
| Potato-dextrose broth         | .. | 45.0            | White later greenish   | Moderate                          |
| PD broth + yeast + peptone    | .. | 181.0           | White later brownish   | Excellent                         |
| Rice meal-dextrose            | .. | 83.0            | White later yellowish  | Poor                              |
| Oat meal-dextrose             | .. | 13.0            | Greenish white         | ..                                |
| Corn meal-dextrose            | .. | 46.0            | White later dark green | Moderate                          |
| Richards' medium              | .. | 29.0            | Greenish-brown         | ..                                |
| Czapek's medium               | .. | 23.0            | Gelatinous             | ..                                |
| Brown's medium                | .. | Traces          | Gelatinous             | ..                                |
| Asthana and Hawker's medium   | .. | 10.0            | Gelatinous             | ..                                |
| Sartoris medium               | .. | 36.0            | Yellowish-green        | Poor                              |
| Yeast extract-dextrose medium | .. | 14.0            | Gelatinous             | ..                                |

Fig. 2. Growth and conidial (sclerotial) formation on YPPDA medium.

100 mg; potato 200 g; dextrose 20 g; agar 20 g and distilled water 1000 ml). The conidia collected from fresh sclerotial balls were dusted over it. A drop of sterilized distilled water was placed at the border of the coverslip at two places and then incubated at 23° C spores germinated within 24 hrs and catches the medium. Clusters of 'sporidia' or secondary conidia were formed at the hyphal tip. Sometimes the growth of hyphae was slow for that 4-5 ovaries of susceptible variety of paddy flowers removed aseptically, placed over the coverslip and crushed in distilled water. This accelerates that growth of germtube of the germinating spore. When considerable development of the hyphae from the germinating spores occurs, it is removed aseptically and placed in the petridish containing YPPDA medium. A dense white aerial mycelium was formed, which produced large, round masses (sclerotia) in about a month (Fig. 2). These were first white, compact and almost round; later on they became orange-yellow and finally olive-green and powdery. Spores are produced in abundance from sclerotia, usually round to elliptical, smooth, paler, 3.5 to 5.5  $\mu$  in diam.

Cultures were made by taking 50 ml of the different media in 250 ml Erlenmeyer flasks and sterilizing in an autoclave at 15 lb (121° C) for 15 minutes. The flasks were then inoculated with equal amounts of inoculum and incubated at 23° C for 45 days. At the end of incubation period,

the dry weights of mycelial mats and sporulation (sclerotia with conidia) were recorded.

It is clear from Table I that *U. virens* gives best dry weight on potato-dextrose yeast-peptone medium followed by rice meal, corn meal, potato-dextrose, Santori's, Richards' and Czapek's medium. Growth was scanty on Ashana and Hawker's and Brown's medium. It seems that yeast and peptone in the natural medium (PD broth) exerts a dominating influence on the mycelial growth of the fungus.

Sclerotial formation was excellent on potato-dextrose-yeast-peptone medium. These were at first white and compact and almost round; later they became orange-yellow and finally olive-green and powdery due to abundant conidial production as observed by Seth<sup>2</sup> and Su<sup>3</sup> on Quaker oat medium. It was moderate on potato-dextrose broth and corn meal and poor on rice meal medium. In the present investigation potato-dextrose-yeast-peptone was found to be the best nutrient medium for the growth and conidial production of *U. virens*.

#### SUPPRESSION OF *VERTICILLIUM* WILT BY *RHIZOCTONIA* ROOT ROT OF COTTON

THE wilt (*Verticillium dahliae* Kleb.) and the root rot (*Rhizoctonia solani* Kühn) of cotton were not observed to occur together in the same patch of the field, and in the earlier observed 'wilt sick' patches where root rot had newly appeared, a decline in the incidence of wilt was noticed. Isolates of *R. solani* obtained from cotton roots were found to vary in virulence, some attacking the main roots and rapidly bringing about death of the plants (virulent), while others brought about partial destruction of rootlets and stunting of inoculated plants, but not their death (moderately virulent). In order to examine the possibility of an antagonistic relationship between the wilt and root rot pathogens, soil-plant cultures of the two pathogens were incorporated in soil held in pots at the rate of 1% by weight of unsterilized garden soil and the susceptible cotton variety MCU-5 (*Gossypium hirsutum*) was raised thereon. One of the virulent isolates of *V. dahliae* and two isolates of *R. solani* differing in virulence were used. The results are given in Table 1.

TABLE I  
Incidence of wilt and root rot in the presence  
of the two pathogens

| Inoculum                                  | No. of plants<br>affected<br>out of 20 |          |
|---|--|----------|
|   | Wilt                                   | Root rot |
| <i>V. dahliae</i>                         | .. 20                                  | ..       |
| <i>R. solani</i> (virulent)               | .. ..                                  | 19*      |
| <i>R. solani</i> (moderately virulent)    | .. ..                                  | 16†      |
| <i>V. dahliae</i> + <i>R. solani</i> (v)  | .. 1                                   | 17*      |
| <i>V. dahliae</i> + <i>R. solani</i> (mv) | .. 3                                   | 15†      |

\* Plants killed; † Plants not killed, but stunted.

While the presence of *R. solani*, either of the virulent or of the moderately virulent type, inhibited the incidence of wilt, the presence of *V. dahliae* did not appear to influence the incidence of root rot. Isolations made from roots and stems failed to yield cultures of *V. dahliae* indicating that invasion of the vascular system by the wilt pathogen had been prevented in the presence of *R. solani*. Similar results were obtained when "wilt sick" soil was infested with *Rhizoctonia* inoculum and also when inocula were applied to the roots by the 'root dip' technique using suspensions of conidia and mycelia respectively of the wilt and root rot pathogens.

The chemical PCNB which is specific for the control of *Rhizoctonia* was applied to patches of fields where stray incidence of wilt was noticed but root rot occurred on a large scale. It was applied as 'brassicol' at the rate of 10 kg per acre and well mixed with the top 9 inches of soil. The incidence of root rot decreased from 80 to 85% in the untreated spots, to 10 to 15% in treated spots, while the incidence of wilt increased from 3% to 33 to 45%.

In culture, *R. solani* grew much faster than *V. dahliae* but no evidence of mycelial invasion of *Verticillium* or of the elaboration of an antibiotic substance was obtained. *In vivo* also *R. solani* rapidly invaded cotton roots bringing about destruction of root tips and maceration of cortical tissue within 24 hours of inoculation. On the other hand, according to Garber and Houston<sup>1</sup>, *V. dahliae* takes at least 3 days for effecting entry into the cortical tissue of the root and reaching the vascular system. Thus it appears that *R. solani* achieves a pre-emptive seizure and destruction of the portals of entry and blocks infection by *V. dahliae*.

The use of PCNB for controlling root rot has to be viewed with caution and should be precluded from areas with a hazard of *Verticillium* wilt.

# EFFECT OF DOWPON ON THE CONTENT OF PROTEIN AND PROTEOLYTIC ACTIVITY IN *CYNODON DACTYLON* PERS.

DOWPON (2,2-dichloropropionic acid) being a propionic acid compound, its mode of action differs from that of 2,4-D and other triazine compounds in several respects. Redemann and Hamaker<sup>1</sup>, and Choudhri<sup>2</sup> reported that dalapon is an efficient protein precipitant. Foy<sup>3</sup> has shown that dalapon is a fairly strong acid and a protein precipitant. Four concentrations of dowpon were used and the protein content and proteolytic activity<sup>4</sup> in the foliage were estimated at four intervals after application (Table I). The results show that the medium

the enzyme complex generally. The proteolytic activity of the enzyme is phenomenally increased by the herbicide at the concentration employed resulting in the precipitation of protein. The mode of action is primarily on immobilisation of protein an index of toxicity of the herbicide.

The senior author is thankful to the Indian Council of Agricultural Research for awarding the Junior Fellowship during the tenure of M.Sc.(Ag.) Course.

The values in parenthesis are the activities in micrograms/g.

concentration (10 kg/ha) increased the protein content slightly at the end of 4 days ; but 8 days after the spray all the concentrations reduced the protein content throughout.

In general, the proteolytic activity increases with an increase in the concentration of the herbicide for a given interval of time. Similarly the activity of a given concentration increases with the period upto 12 days and then there is a fall.

The proteolytic enzyme generally hydrolyses the protein molecule into other fractions of nitrogen. Higher activity of this enzyme results in greater hydrolysis of protein. Freiberg and Clark<sup>5</sup> recorded a similar observation in stem and shoots of soyabean using 2, 4-D. Leisure<sup>6</sup> stated that the effect of dalapon as a protein precipitant would inactivate

## AN UNREPORTED LINKAGE GROUP IN RICE (*ORYZA SATIVA* L.)

INHERITANCE of purple pigment in coleoptile, auricle and glume was studied in a rice cross between T-141, a variety developed by the Orissa State Department of Agriculture and K-44-1 an improved scented variety of the Karnataka State. F<sub>1</sub> showed the presence of purple pigment in these parts and F<sub>2</sub> population consisting of 2,624 individuals was studied (Table I). F<sub>3</sub> behaviour confirmed the F<sub>2</sub> ratios. Joint segregation of these characters is presented in Table II.

TABLE I  
Character expression of parents,  $F_1$  and  $F_2$  segregation in T-141 and K-44-1

PP = Both purple; PW and WP = Recombinant classes; WW = Both white.

Coleoptile segregated in the ratio of 39 purple : 25 white indicating the interaction of three genes—a basic gene ( $A$ ), an inhibitory gene ( $I-Pc$ ) and an anti-inhibitory gene ( $Ai-Pc$ ). Auricle is governed by five pairs of factors—two complementary ( $A$  and  $Pau_a$ ), one inhibitory ( $I-Pau$ ) and two anti-inhibitory-complementary ( $Ai-Pau_a$ ,  $Ai-Pau_b$ ) giving a ratio of 387 : 637. Glume is conditioned by four genes—one basic ( $A$ ), one complementary ( $Pg_a$ ), one inhibitory ( $I-Pg$ ) and one anti-

inhibitory ( $Ai-Pg$ ) suggested by the ratio of 117 : 139.

The ratios of 39 : 25 for coleoptile colour, and 387 : 637 for pigment in auricle are reported for the first time and the ratio of 117 : 139 realised in the case of glume colour is in confirmation with that reported by Ghose *et al.*

The combined segregation presented in Table II has revealed interesting results. These three characters showed the presence of one pleiotropic gene common

to all of them which may be one of the basic-complementary genes designated as *A*. Further analysis indicated the association of these characters. Linkage was detected between the anti-inhibitory genes concerned with them and the cross-over values suggested the sequence of the genes as *Ai-Pg*, *Ai-Pc* and *Ai-Pau* (Fig. 1). Map distances were revised as per the Kosambi formula (Kosambi<sup>3</sup>) and the corrected cross-over value is shown in the parenthesis.

FIG. 1. Linkage map showing relative positions of *Ai-Pg*, *Ai-Pc*, *Ai-Pau* genes. Cross-over values are given in percentages.

Linkage groups in rice have been tentatively constructed by Jodon<sup>2</sup>, Ramiah<sup>7</sup>, Misro *et al.*<sup>4</sup>, and Nagao and Takahashi<sup>5,6</sup> and the linkage group identified and reported for the first time in this paper has not been referred to by them.

The authors are grateful to the United States Department of Agriculture for having financed this research by a grant made under PL. 480.

#### NEPHOTETTIX VIRESCENS (DISTANT) NYMPHS AND THEIR ROLE IN THE SPREAD OF RICE TUNGRO VIRUS

RICE tungro virus (RTV) is transmitted by both adults and nymphs of *Nephotettix virescens*<sup>1</sup>. While adults have good mobility, the movement of the nymphs is restricted. Their role in disease

spread is not clearly understood. A replicated experiment was, therefore, set up under field conditions during *Rabi* 1974, using field cages to study the role of nymphs in spread of RTV.

Sixty-three rice plants [Taichung (Native)<sup>1</sup>] with a spacing of 15 × 20 cm were covered by a field cage measuring 1½ × 1½ × 1 meter immediately after transplantation. Twelve such cages were set up. Ten days after transplantation, the middle plant in each cage was replaced by a diseased plant (same cultivar) and caged by cellulose butyrate tubes of 2" diameter. Sixty individuals of each of five instars and adult stages were introduced into each tube separately in a field cage. Leaf hoppers at different stages of development were allowed to feed on the diseased plant for 24 hours to acquire the virus. After acquisition feeding period the cellulose butyrate tubes were lifted and the viruliferous leaf hoppers allowed to migrate on to the healthy plants within the field cage for 24 hours. At the end of this period, the insecticide Carbofuran was used to kill the leaf hoppers. The amount and pattern of infection was recorded 20 days after Carbofuran treatment.

The average percentage of transmission and distance travelled (as indexed by virus infection) by each instar nymph and adult are given in Table I.

TABLE I  
The role of nymphs of *Nephotettix virescens* in spread of rice tungro virus

| Stage of the vector  | Average % infection | Maximum distance travelled in a 85 cm radius within the cage |
|----------------------|---------------------|--|
| First instar nymphs  | 1.6                 | 20   |
| Second instar nymphs | 4.2                 | 35   |
| Third instar nymphs  | 10.1                | 60   |
| Fourth instar nymphs | 18.5                | 75   |
| Fifth instar nymphs  | 20.0                | 75   |
| Adults               | 19.5                | 85   |

The average percentage transmission by first to fifth instar nymphs and adults was 1.6, 4.2, 10.1, 18.3, 20.0 and 19.5, respectively. The later three stages of the leaf hopper could travel for longer distance than the earlier three stages. The third, fourth and fifth instar nymphs and adults were capable of spreading the disease more efficiently than the first and second instar nymphs. The infected plants were located near the inoculum, source in the case of the first, second and third instar nymphs, whereas the fourth and fifth instar nymphs and adults caused infection throughout the field cage though more infected plants were in the vicinity of the inoculum source,

Under natural conditions nymphal populations may be more in number than the adult, especially in the active tillering stage of the crop in the field. It appears, therefore, that nymphs, in all probability, are playing a greater role in disease spread within a field. Presumably, while the adults can bring the primary inoculum to the field, nymphs may aid in secondary spread of the virus. This mechanism may explain the occurrence of the disease in patches (mostly circular) in the initial stages of infection under natural conditions.

The author is grateful to Dr. S. Y. Padmanabhan, Director, for his interest and encouragement and thankful to Dr. N. K. Chakrabarti, Head of Plant Pathology, for providing facilities.

#### SHEATH BLIGHT AND WILT OF RAGI (*ELEusine CORACANA* GAERTN.) CAUSED BY *MARASMIUS CANDIDUS* BOLT.

WILT, disease of ragi (*Eleusine coracana* Gaertn.), a cultivated millet, caused by *Sclerotium rolfsii* Sacc. (Curzi) has been reported to be important in Tamil Nadu and other regions<sup>1</sup>. During the months of June-July 1974, Co. 10, a popular variety of ragi, was found affected to a very serious extent by a sheath blight and wilt in the campus of the Tamil Nadu Agricultural University, Coimbatore. On the sheaths of the affected plants, to a distance of about 5-15 cm from the ground level, characteristic circular to elliptic, necrotic blotches were observed as early symptoms of the disease. As the disease advanced, the sheaths got stuck or bound together, with the mycelium of the fungus, to the stem, eventually leading to wilting and the death of the plants. The diseased plants in a field could be easily distinguished by the discoloured or dried up outer leaves. On lower sheaths of the dead plants small sporophores of a mushroom were noticed. Isolations from the sheaths of the diseased plants yielded a fungus with milky white mycelium. As no sporulation could be obtained, inoculations were made on healthy Co. 10 ragi plants, raised in pots for the purpose, by placing mycelial bits on the sheaths, wrapping them with moist cotton and covering the cotton with a polythene strip to maintain the humidity. Characteristic blight type lesions developed on the inoculated sheaths within a week. Soon the outer leaves turned yellow and dried and the plants eventually succumbed a month after inoculation.

Sporophores of the mushroom developed in 45 to 50 days after inoculation, on the lower ends of the stems thereby proving its pathogenicity.

The fungus is identified as *Marasmius candidus* Bolt. The mushroom is white, delicate, leathery and dry, does not easily decay, but shrivels up in dry weather, and revives in wet weather or when placed in water; pileus membranous, semi-spherical, pellucid, wrinkled; stipe thin; spores hyaline, elliptical to ovate, smooth and measure  $4 \times 2 \mu$ . Basidia four-spored, hyaline; systidia sub-cylindric to ventricose at the basal portion, hyaline and thin; gill trama of loosely interwoven hyphae. These characters agree with other descriptions of *M. candidus* (Bolt)<sup>2,3</sup>.

Quite a few species of *Marasmius* have been known to be pathogenic on cultivated crop plants. *Marasmius sacchari* Wakker, associated with a root necrosis of sugarcane; *M. semiustus* B. et C. (*M. stenophyllus* Mont.) causing death of dryland rice in Malaya<sup>4</sup>, *M. tritici* Yg. on green plants of wheat, rye, barley and quackgrass are a few examples. With the exception of *Pellicularia* (*Sclerotium*) *rolfsii* no other organism has been known to cause wilt of ragi, and this is the first record of sheath blight and wilt caused by *Marasmius candidus* Bolt.

#### GROWTH INHIBITORS FROM *PARTHENIUM HYSTEROPHORUS* LINN.

PRESENCE of water soluble inhibitor(s) in the fruits and receptacles of *Parthenium hysterophorus* Linn. has been reported earlier from our laboratory<sup>1</sup>. Further experiments were carried out to test if other parts of the weed also contained the inhibitor(s) and to determine the relative concentration in different parts.

The air dried root, stem, leaves, inflorescence and fruits of mature plant of *Parthenium hysterophorus* (0.5 g each) was fragmented and after surface sterilising with 0.1% mercuric chloride and subsequent thorough washing was spread with wheat grains on moist blotters in petridishes at the rate

of six grains per dish and the entire set was replicated five times. Germination and growth of 72 hr old seedlings of wheat were studied. Figure 1 shows that inhibitor(s) is present in all parts of the weed. The concentration of the inhibitor is highest in leaves followed by inflorescence, fruits, roots and stem.

FIG. 1. Parts of the weed tested. 1. Leaves, 2. Inflorescence, 3. Fruits, 4. Roots, 5. Stem.

Further, to analyse the inhibitor complex, to identify the prominent components and to test them for their inhibitory activity, 250 g of air dried stem were cut into small pieces and kept soaked in distilled water for 48 hrs, for the complete leaching out of the inhibitor. Three litres of the brown diffusate were filtered and concentrated to 200 ml. From this the inhibitor(s) was extracted with successive addition of ethyl acetate upto a final volume of 500 ml. The ethyl acetate extract was distilled under reduced pressure at 50–60° C. The thick brownish residue was divided into acidic and non-acidic fractions by extracting the former with 0.1N sodium bicarbonate. This fraction was acidified to pH 2.5 with concentrated HCl and then, the inhibitor was extracted with ethyl acetate (50 ml). This fraction was washed thoroughly with water and concentrated as was also the non-acidic fraction.

The two fractions were run on TLC plates using silica gel and benzene-ethyl acetate 70:30. The spots were developed in an iodine chamber and their  $R_f$  values were calculated. The non-acidic fraction showed 6 spots ( $R_f$  0.88, 0.61, 0.45, 0.28, 0.09). One with the  $R_f$  0.28 was prominent and intense brown. The non-acidic fraction was also chromatographed over acidic alumina column packed with petroleum ether. Petroleum ether

followed by petroleum ether-ethyl acetate 70:30 was run through. The first fraction that was collected crystallised instantaneously and the total yield was 560 mg. The melting point of these crystals was determined and it agreed with that of parthenin (163–166°)<sup>2</sup>. This was further confirmed by chromatographic comparison with an authentic sample of parthenin. This crystalline compound when cochromatographed corresponded to the intense brown spot on the TLC plate referred to earlier. It is interesting to note the presence of parthenin in the aqueous diffusate; it was earlier isolated<sup>2</sup> from petroleum ether and chloroform extracts of the whole plant.

The acidic fraction gave five spots on TLC plate ( $R_f$  0.44, 0.32, 0.20, 0.10, 0.04). The prominent spot with  $R_f$  0.20 was eluted with methanol. Its bright fluorescence under UV light and colour reactions (alcoholic  $\text{FeCl}_3$ -green, bromine water-decolouration,  $\text{AgNO}_3$ -reduction, Gibb's reagent-pink colour) indicated that the compound was a phenolic catechol type, unsaturated acid. Cochromatography with an authentic sample revealed this to be caffeic acid. Using ragi coleoptile bioassay method, the total yield of caffeic acid in the sample was 78 mg.

The spot ( $R_f$  0.32) showing weak fluorescence under UV light, becoming intense on exposure to ammonia and decolourising bromine water, indicated the presence of *p*-coumaric acid. Cochromatography with a pure sample confirmed this.

All the spots in both the acidic and non-acidic fractions were tested for inhibition of growth in the seedlings of ragi (*Eleusine coracana* variety 'Poorna'). All of them except the one with  $R_f$  0.12 in the acidic and  $R_f$  0.46 in the non-acidic fraction answered the test positively.

Thus it may be concluded that all parts of the weed *Parthenium hysterophorus* contain inhibitor(s), its concentration being greatest in the leaves followed by inflorescence, fruits, root and stem. The inhibitor is a complex. Parthenin, caffeic acid and *p*-coumaric acid are the prominent constituents of the inhibitors from the stem.

### PREVALENCE OF A MOSAIC DISEASE ON FRENCH BEAN IN KUMAON

DURING a survey for virus diseases of cultivated plants in the hilly tracts of Kumaon, Uttar Pradesh, the authors observed French bean (*Phaseolus vulgaris* L.) affected by a mosaic disease in almost all the plots surveyed. The disease incidence varied from 5 to 60%. This caused concern to the growers because French bean is an important vegetable and pulse crop in that area. The diseased plants show varying degree of mottling or chlorosis (Fig. 1), blistering, downward cupping of the lamina. They are rarely killed by the disease but become stunted, dwarfed and bushy depending upon the variety, time of infection and different virus isolates involved. They shed their flowers more freely than the healthy plants and the setting of the pods is adversely affected. This results in loss of yield, in some cases up to 100%.

FIG. 1. Infected leaf of French bean.

The disease was mechanically transmitted to a number of bean varieties which include Bountiful, Canadian Wonder, English tender pod, Giant stringless green pod, Masterpiece, Premiar, Prince, Stringless black valentine, Superlative and a few unidentified popular local varieties. All attempts to transmit the disease to the following plants were unsuccessful:

*Brassica oleracea* L., *Capsicum annum* L., *Cucurbita pepo* L., *Cucumis sativus* L., *Datura metel* L., *D. stramonium* L., *Dolichos lablab* L., *Lycopersicon esculentum* Mill., *Nicotiana debneyi* L., *N. glauca* L., *N. tabacum* L. var. *Harrisan special*, *N. rustica* L., *Pisum sativum* L., *Vicia faba* L., *Vigna sinensis* (L.) Endl., and *Zinnia elegans* Jacq.

*Aphis gossypii* Glov. and *Myzus persicae* Sulz. proved to be the most efficient vectors of the virus and transmitted it in a non-persistent manner.

The virus was inactivated at a dilution of 1 : 1000 at temperatures between 55–60° C. Its longevity *in vitro* was 24–32 hours at room temperature (20–22° C). The disease was also transmitted through seed.

Iwanowski<sup>1</sup> was the first to record a mosaic disease of bean from Russia. This was followed by reports of the disease in North America, Australia, South Africa, New Zealand, China, France and Iran. The present study indicates that the virus, responsible for the disease, is a strain of *Phaseolus* virus I similar to that reported by Smith<sup>2</sup>. As regards control, the only method that could be suggested to the farmers is the use of seeds from healthy plants followed by rouging of infected plants. But use of resistant bean varieties would be the best method to get rid of the disease. At present we do not have any resistant variety which could be recommended.

Our sincere thanks are due to Prof. K. S. Bhargava for encouragement and providing the necessary facilities.

### OCCURRENCE OF *RHIZOSOLENIA COCHLEA* BRUN (BACILLARIOPHYCEAE) IN PORTO NOVO WATERS

THE present communication deals with the occurrence of *Rhizosolenia cochlea* (Figs. 1, 2) in the neritic waters (Bay of Bengal) of Porto Novo. The species is usually rare in occurrence in coastal areas, although it was reported from Nancowry (Nicobar). (Desikachary—personal communication). The distribution of this species has been discussed recently by Sournia<sup>1</sup> where he mentions about the rarity of this species in the Indian Ocean, reporting its occurrence from restricted regions elsewhere (Siam, Hong-Kong and Japan).

Specimens were isolated from phytoplankton samples collected at the ten fathom lime using a No. 25 bolting silk net on 14th June, 1974. The salinity of the surface water was 35.4‰ and the surface temperature 27.5° C. The technique of

preparing frustules for examination was that given by Hendey<sup>2</sup>.

FIGS. 1-2. Fig. 1. Recently divided cells. Fig. 2. Part of a cell enlarged to show intercalary bands.

There was agreement with the description given by Sournia<sup>1</sup> except in size: the present material measured 58 to 63  $\mu\text{m}$  in diameter (and a range of 50 to 75  $\mu\text{m}$  is also known—Desikachary—personal communication), whereas the range reported by Sournia was 80–130  $\mu\text{m}$ .

The populations of diatoms counted by using the sedimentation technique and an Utermöhl inverted microscope were  $7.4 \times 10^3$  cells/l, of which the population of *R. cochlea* alone was  $4.8 \times 10^2$  cells/l. The associated dominant species were *R. imbricata* Brightwell, *R. calcaravis* Schultze, *Guinardia flaccida* (Castracane) Peragallo, *Bacteriastrium hyalinum* Lauder and *B. delicatulum* Cleve.

Twelve species of *Rhizosolenia* have so far been collected from Porto Novo waters.

The other interesting and rare phytoplankton species observed in these waters were *Chaetoceros glandazii* Mangin (= *C. rostratum*), *C. subtile* Cleve, *Synedra crystallina* (Agardh) Kuetzing and *Campylodiscus echeneis* Ehrenberg among diatoms and *Amphisolenia schroederi* Kofoid and *Oxytoxum elongatum* Wood among dinoflagellates.

The salinity recorded in the present instance (35.4‰) was rather high for Bay of Bengal waters, about the same as the salinity of the Indian Ocean waters. It is known that the South West Monsoon drift (surface current) from April to October flows eastward south of India, with its branches flowing clockwise, following the coastline in the Arabian Sea and the Bay of Bengal<sup>3</sup>. It is possible that *R. cochlea* and some other species could have travelled from the West Indian Ocean (off Madagascar and Africa).

Our grateful thanks are due to Prof. R. Natarajan, Director, for the facilities provided and for constant encouragement. Our profound thanks are also due to Prof. T. V. Desikachary, Centre of Advanced Study in Botany, The University of Madras, and to Dr. A. Sournia of Museum National D' Histoire Naturelle, Paris, for a critical reading of the manuscript and for very helpful comments. One of us (R. S.) is grateful to the University Grants Commission, New Delhi, for the award of a Junior Research Fellowship.

#### RATIO OF RAY AND FUSIFORM INITIALS IN THE VASCULAR CAMBIUM OF SOME ARID-ZONE PLANTS

As far back as 1923, Bailey<sup>1</sup> had noted that the fusiform cells occupy approximately seven-eighth of the total circumference of the cambial zone in *Pinus*, a much lesser proportion in many dicotyledons and a little less than one half in certain extreme cases. But recently Wilson<sup>6</sup> calculated the surface area of the different cambial initials in *Abies concolor* and found that the fusiform cells form more than 90% by volume of the cambium and its derivatives. Based on the above, Wilson<sup>7</sup>, in the year 1964, proposed a model for the cambium of conifers. Following this, Kozłowski<sup>5</sup> (p. 7) also noted a similar composition for the cambium in general in his book on "Growth and development of trees". Butterfield's<sup>2</sup> recent observations on

*Aeschynomene hispida* also made it clear that the fusiform cells may form more than 95% of the cambial population in certain cases.

Contrary to the above, Ghouse and Yunus<sup>4</sup> observed that the fusiform cells do not constitute more than 60% of the cambium in the fully grown trees of *Dalbergia*, although their magnitude may go up to 80% in the young trees. Again these authors found the fusiform cells forming only 25% of the cambial population in one of the tropical trees, viz., *Dillenia indica* (in Press).

Keeping in view the above developments, the present work was undertaken with an aim to find out in what proportion the fusiform and ray initials occur in the cambial zone of certain arid-zone plants.

Cambial samples, along with some conducting phloem, and sapwood collected (20 samples per species) from the main trunks of *Acacia catechu* Willd., *A. farnesiana* Willd., *A. melanoxylon* R.Br., *A. nilotica* (Linn.) Willd. var. *kauria* or *vedi*, *A. nilotica* var. *Ramkanta* or *Ramkati*, *A. nilotica* var. *telia* or *godi*, and *Prosopis spicigera* Linn., fixed in F.A.A., preserved in 70% ethanol were sectioned on a sliding microtome in tangential plane at a thickness of 10–12  $\mu$ , stained with tannic acid-ferric chloride<sup>3</sup>, mounted in Canada balsam after dehydration in ethanol series and studied. Camera lucida diagrams were made on tracing paper, out of all samples and the portions containing ray initials were removed and weighed. The portions containing fusiform initials (after removing ray initials) were then weighed separately. The weighing was done on a sensitive chemical balance. The proportion of fusiform initials to ray initials per unit area was calculated on the basis of the weights thus obtained.

Analysis of the data obtained in the present study revealed, that the fusiform cells constitute at their maximum about 82% of the total tangential area of cambial zone in *A. melanoxylon*. This is closely followed by *A. farnesiana* and *A. nilotica* var. *Ramkanta*, in which the fusiform initials occupy 78% and 75% of the total tangential area respectively. In *A. catechu* fusiform cells occupy about 70% while in the other two varieties of *A. nilotica*, viz., *telia* and *kauria*, the fusiform cells form about 62% and 57% respectively. In case of *Prosopis* the fusiform cells take about 63% of the total tangential area, while the remaining 37% of the cambial zone is occupied by the ray initials (Fig. 1).

The results, thus, clearly indicate that in no species, investigated the proportion of fusiform cells exceeds more than 82% (57–82% in *Acacia* and 63% in *Prosopis*), and assume a magnitude of

90% or more, as it was reported by some earlier workers<sup>2,5-7</sup>.

Fig. 1

The second author (M. Y.) is very thankful to the Council of Scientific and Industrial Research, New Delhi, for the award of a Senior Fellowship. The laboratory facilities provided by Prof. R. Khan, are being gratefully acknowledged by all.

#### A NEW GRASS FROM NEPAL

Borl<sup>1</sup> has mentioned 18 taxa of genus *Eulalia* Kunth (Poaceae). One more new taxon has been found from Nepal. This new taxon is named and described here as *Eulalia trispicata* (Schult.) *Henr. var. hookeri* P. Sur var. nov.

*Eulalia trispicata* (Schult.) *Henr. var. hookeri* P. Sur, var. nov.

Differt a varietate typica habitu parbiore, Spiculis longioribus, lemmate superiore bilobo, apicibus acuminatis.

This variety differs from *Eulalia trispicata* (Schult.) Henr. mainly in its habit, longer spikelets and bilobed upper lemma with acuminate tips.

FIG. 1. *Eulalia trispicata* (Schult.) Henr. var. *hookeri* P. Sur var. nov. A, Sessile spikelet; B, Lower glume; C, Upper glume; D, Lower lemma; E, Upper lemma; F, Stamens and pistil.

*Culms* 25 cm long, slender, branched. *Leaves* 3–15 cm long and 1–2 mm broad, narrowly linear, glabrous; *ligules* short, membranous, fringed with long hairs. *Racemes* 4–6, narrow, 3–5 cm long, compressed; pedicels of spikelets flattened. *Sessile spikelets* 3–3.5 mm long. *Lower glume* 3 mm long, membranous above with a hyaline tip; margins narrowly incurved, villous with long silky hairs. *Upper glume* 3.5 mm long, oblong; margins 1-nerved incurved. *Lower lemma*—empty, 3.5 mm long, narrowly oblong, hyaline, flat, nerveless. *Upper lemma* 3 mm long, linear-oblong, divided into two lobes; lips of lobes acuminate; awns slender, 12–13 mm long, *palea* absent. *Anthers*—3, 3 mm long. *Pedicelled spikelets* similar to the sessile.

*Holotype*: Nepal, Kukhure Dol (Phul), Alt. 7000 ft, 5 October 1967, Mrs. Prodhan 7472 (CAL).

*Etymology*: The grass is being named in honour of the well-known botanist Sir J. D. Hooker.

I am grateful to Deputy Director and Keeper, Central National Herbarium, Howrah, for their encouragement, Dr. R. B. Mazumder, Systematic Botanist, for valuable suggestions and Dr. N. C. Mazumder, for Latin diagnosis.

### DEVELOPMENT OF EMBRYO IN *STELLARIA GLAUCA* WITHERING (CARYOPHYLLACEAE)

THE embryology has been a fascinating subject to many embryologists. Very few contributions have appeared so far on the development of embryo of the members of Caryophyllaceae family<sup>1</sup>. Recently, Pal and Murty<sup>2</sup> have described the embryo development in *Stellaria aquatica*. The present note gives some information regarding the development of embryo in *S. glauca*.

The zygote first divides by a transverse division forming a terminal cell *ca* and a basal cell *cb* (Fig. 1). The basal cell *cb* remains undivided

FIGS. 1–8. Figs. 1–6. Stages in the development of embryo. Fig. 7. A globular embryo with a short suspensor and vesicle like basal cell. Fig. 8. Mature embryo showing procambial strand.

the embryo now takes further part in the development of primary and tertiary large vascular structures (Figs. 2-7). The terminal cell in undergoes transverse division and thus two cells are formed, an upper and a lower cell (Fig. 2). The cell of upper undergoes a transverse division and gives rise to *Q* and *P* (Fig. 3). The cell of lower divides transversely, forming *Q* and *P* (Fig. 4). Thus a row of four cells is formed from *Q* and *P*. Of these the inner cells (*Q* and *P*) divide by a vertical division and the outer cells (*Q* and *P*) shows a transverse wall (Fig. 5). The embryo now shows the formation of *Q* and *P*. In *Q*, a vertical wall is also developed (Fig. 6). In *P*, a transverse wall is formed (*Q* and *P*) (Fig. 7). In this way six tiers of cells are formed. The tier *Q* gives rise to stem tip, the completion of the culm up to root cap and *O*. *P* is short suspension.

A further embryo (Fig. 8) is formed with a short suspension and a very low basal cell, as a result of further divisions of *Q* and *P*. In the usual way, stem tip, cotyledons, etc., get differentiated (Fig. 8). When differentiation is complete there is formation of proembrya strands (Fig. 8). Thus the embryo development conforms to *Carpophyllid* type, as has been reported for *Salicornia*, *Apetalia*, *Stenandria* and *S. aquatica*.

The author is greatly indebted to Prof. Y. S. Murty for encouragement and Dr. V. Singh for providing the facilities and for his keen interest.

### CULMS IN CYPERUS

IN an attempt to the anatomy of Cyperaceae, Metcalfe (1971) has stated that culm anatomy of *Cyperus esculentus* somewhat resembles *Cyperus articulatus*. David-Jouve (1974) examined the culm anatomy of *Cyperus aureus* which he considered identical with *C. esculentus*. Anderson (1888), Plowman (1906), Buchholz (1921), Greiss (1957), Morita (1963), Shyam (1963), Shah (1967), Mehra and Sharma (1970) and Fisher (1970) have described the stem anatomy of many species of *Cyperus*, but *C. esculentus* is least mentioned. D'Almeida and Ramaswamy (1948) studied the anatomy of 10 Indian species of *Cyperus*,

but *C. esculentus* is not worked out. Thus, the literature shows that the details of the culm anatomy of this species have not received due attention by anatomists.

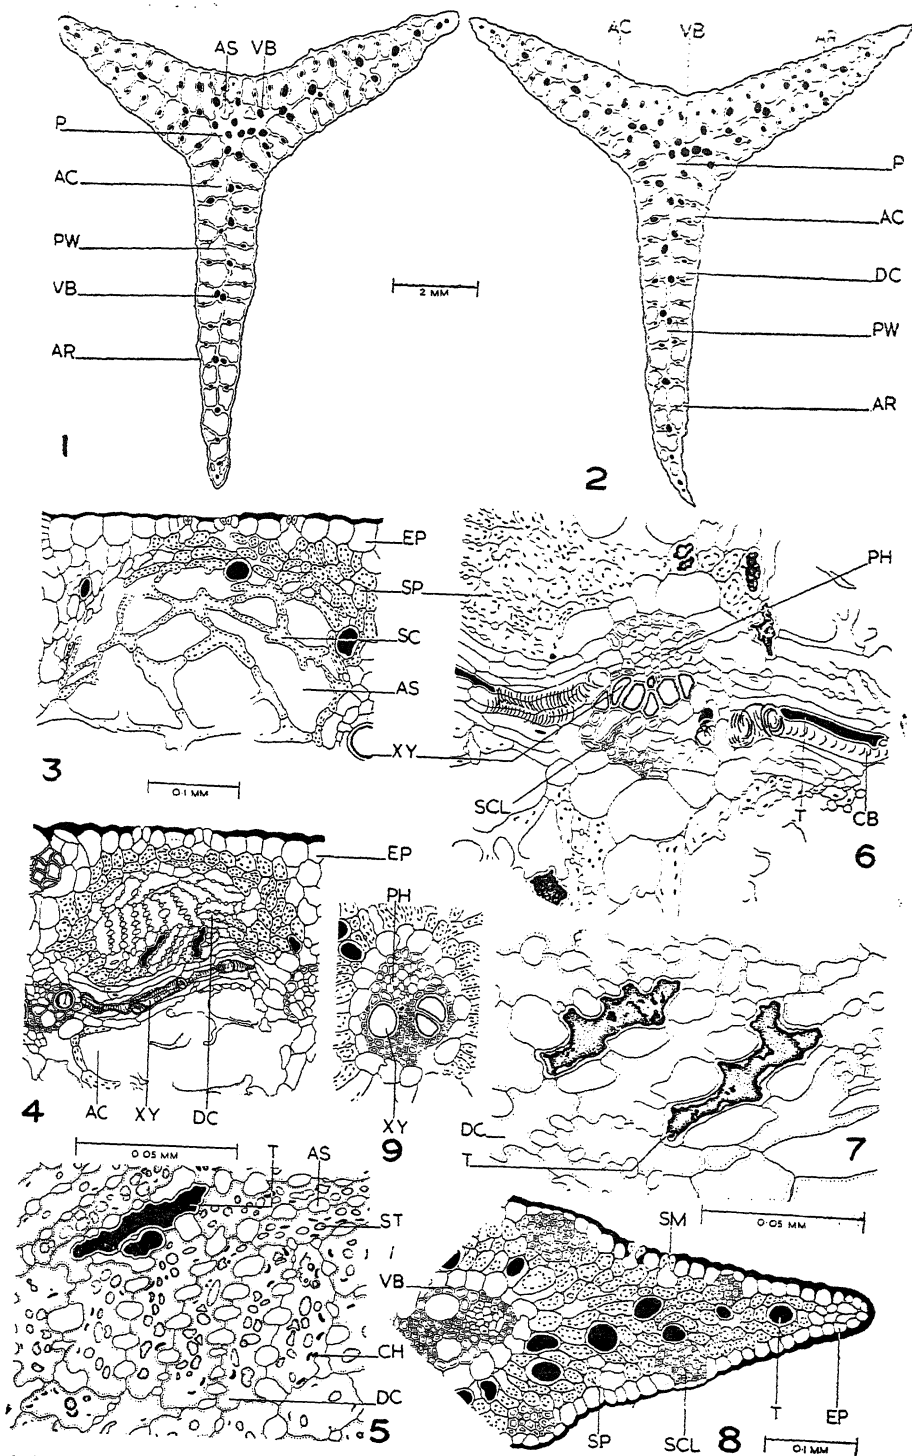

The inflorescence axis or the culm of *C. esculentus* is easily distinguished by its considerable length and triangular outline. It is straight and unbranched, and arises singly. The maximum length of the culm recorded in the month of August was 176 cm. Underground part of the culm is delicate and white, while the aerial part assumes a light green colour.

Culm is Y-shaped in a cross-section (Fig. 1). Many continuous air canals, separated by thin, delicate partition walls of parenchymatous cells (Figs. 1 and 2), are present all along its length. Partition walls are only one cell thick (Fig. 3). The many vascular bundles lie at intersections of these partition walls. These air canals are divided into a number of small compartments by horizontal partition walls forming diaphragms (Fig. 4). Diaphragms have also been recently reported in the leaves of this species by Shyam and Sharma (1974). These diaphragms are always supported by a cross-bundle which connects the two main bundles, running longitudinally throughout the body of the culm (Figs. 4 and 6).

The inner borders of these air canals are lined by parenchymatous cells containing abundant chloroplasts. But in the centre of the compartment, there are many small intercellular spaces, which give the walls, a beaded appearance in transverse section (Fig. 3). Diaphragm cells vary from polygonal to stellate in shape. These are present in groups, and are very long, but narrow, with short arms (Fig. 4). More cytoplasm is present in the diaphragm cells in comparison to that of the other cells (Fig. 5). They also contain some starch grains, and some of the diaphragm cells are completely filled with tannin (Fig. 7). The cross-bundles are made up of xylem and phloem, which are connected with the xylem and phloem of the longitudinal bundles of the culm (Fig. 4). Sometimes, a single longitudinal bundle is seen, connected with the two cross-bundles on either side (Fig. 6).

The longitudinal bundles of the culm are exclusively collateral, and have fiber cells on their outer side. The bundles are arranged in two sets, the outer alternating with the large air canals, and are arranged along the entire length of the arm of culm in two rows, while the inner are irregularly scattered in the culm (Fig. 2).

However, at the three angles of the culm, the margins are extremely pointed (Fig. 2). They are interrupted by two to three vascular bundles in a single row. The xylem and phloem are completely

Figs. 1-9. Figs. 1-2. Serial transverse sections of culm passing from base upwards at different levels. Fig. 3. T.S. of culm showing the stellate cells in the air canal. Fig. 4. (AC, air canal; AR, arm of culm; AS, air space; CB, cross-bundle; CH, chloroplasts; DC, diaphragm cells; EP, epidermis; P, parenchyma; PH, phloem; PW, partition wall; SC, stellate cell; SCL, sclerenchyma; SM, stoma; SP, spongy parenchyma; ST, starch grain; T, tannin; VB, vascular bundle; XY, xylem.)

separated in the mature bundles by a plate of sclerotic tissue (Fig. 9). Chlorophyllous parenchyma forms a compact layer underlying the epidermis. The mechanical tissue of the culm is confined to a few, very small, hypodermal ribs, and a few sclerenchymatous strands above the partition walls, separating the air canals and surrounding the vascular bundles. These hypodermal ribs are more prominent in the angles of the culm (Fig. 8), and are composed of small sclerenchymatous cells. All these structures are surrounded by epidermis, which is covered by a thin cuticular layer. The cuticle, though thin, is conspicuous at the extreme edges of the culm (Fig. 8). Over the hypodermal ribs, the epidermal cells are small. Two or three stomata, which are somewhat depressed, open into the air canals.

## SHORT SCIENTIFIC NOTES

### A New Leaf Spot Disease of *Ipomoea carnea* Jacq.

A leaf spot disease of *Ipomoea carnea* Jacq. was observed during the summer season around Madanapalle. The disease is characterised by large irregular dark brown necrotic areas, often lightly flecked with dark conidia. In later stages the central portions fall off giving a 'shot-hole'-like appearance.

The fungus was isolated and pathogenicity proved by spraying the spore suspension on detached twigs. The spores (conidia) were pale brown, muriform, obclavate with long beaks. These conidia with cross (2-7), longitudinal (1-8) and oblique (1-4) septa measure  $36$  to  $75\mu$  (with beak) in length and  $6$  to  $12\mu$  in diameter. The length of the beak varies from  $6$  to  $45\mu$ . The confirmation of the causal organism as *Alternaria tenuissima* (Kunze ex Pers.) Wiltshire by Dr. Ellis of CMI, Ferry Lane, Kew, England (IMI 184577) is gratefully acknowledged.

### Evidence of Polyploidy in *Stephensiella brevipedunculata* Kash.

*S. brevipedunculata* has been cytologically investigated by Mehra<sup>2</sup>, who has reported eight mitotic chromosomes from gametophytic tissue. He did not come across any meiotic abnormality. The present author has also confirmed eight small ( $1.5\mu$ - $2\mu$  long) chromosomes in the androgonial cells, but the findings of meiotic configurations clearly rule out the possibility of this species from Naini Tal to be at the monoploid level.

The thalli of *S. brevipedunculata* grow luxuriantly in different places of Kumaon and the material for the present study was collected from Naini Tal. Young antheridia and sporogonia were collected and fixed in July and August 1973. The method adopted for fixing, etc., was as in the previous case<sup>2</sup>.

On examination of thirty-three dividing spore mother cells, the following groupings of the sixteen chromosomes were observed.

A. In 25% cells, chromosomes were arranged in four groups: each one being a tetravalent.

B. In 60% cells, six groups were observed consisting of two tetravalents and four bivalents.

C. In 9% cells, eight groups were seen, out of which one was tetravalent, five bivalents and two univalents.

D. In 6% cells eight groups of bivalents were observed.

These findings clearly indicate that *S. brevipedunculata* from Naini Tal is at the diploid level with  $2n=8$  and it might have evolved from some haploid member of the Hepaticae with  $n=4$ . This view is in concurrence with the opinion of Berrie<sup>1</sup> and Proskauer<sup>3</sup>, according to whom all the ancestors

### Foot Rot of Wheat Caused by *Fusarium graminearum* Schwabe.

The nature of foot rot and seedling blight of wheat is not fully known in India. Eleven fungi have been reported to cause root rot and foot rot<sup>1-3</sup>. Wheat plants grown at the farm, College of Agriculture, Palampur (H.P.), showed necrosis of culm at soil level. The culm gets blackened and the plants are stunted in growth. Some of the plants are broken from that portion and are lodged whereas the other (in which blackening is less) stand normally. All such plants have smaller ears compared to healthy plants. *Fusarium graminearum* was isolated from such plants from culm portion. The pathogenicity of the fungus was proved by adding the culture to the soil. The seeds were sown afterwards. Only 38% seedlings survived and produced healthy ears. 20% plants died at seedling stage and 42% at maturity time. These plants showed typical foot rot symptoms. This study revealed that *Fusarium graminearum* Schwabe causes foot rot of wheat. *F. graminearum*, though not reported from India, has been known to be a

of *Hepaticae* had evolved from *Takaka* ( $n=4$ ) through doubling of chromosomes.

Mehra's failure to observe evidence of diploidy in species growing in these areas (W. H. and Punjab plains) may have been due to 100% incomplete chromosomal association at pachytene (6% in present findings). He has however reported diploidy in *Asterella reticulata*, *A. blumeana* and *Athalia pinguish*.

I am thankful to Dr. Ram Udar for his guidance during the preparation of this manuscript.

***Polistes hebraeus* (Fabricius) Preying upon *Rhipiphoro-  
thrips cruentatus* Hood (Thripidae:Thysanoptera)**

*Rhipiphorothrips cruentatus* Hood is a polyphagous species and has been reported to feed upon *Vitis* spp., *Lagerstroemia indica*; *Punica granatum* Linn.; *Syzygium jambolana* (Linn.); *Careya arborea* Roxb.; *Anacardium occidentale* Linn.; *Terminalia catappa*, *Mangifera indica* and *Rosa* sp.<sup>1,2</sup>. During survey on pests of ornamental trees and shrubs at Ludhiana in the months of August–November, 1974, rose plants were found to be attracting large number of the workers of the yellow wasp, *Polistes hebraeus* (Fabricius). Observations were, therefore, made on the status of this wasp in the rose ecosystem.

On close observation, the adult wasps were found feeding on the nymphs of the thrips. The workers started their activity at 09 hr and continued till 17 hr daily. On an average, a single shoot of the rose infested by the thrip was visited 14 times per hour and 3–5 minutes were spent per shoot by the nymph searching wasp which located its prey in the young tender shoots with the help of to and fro movements of its antennae. The starved wasps when put in glass jars (10 × 15 cm) along with the rose shoots each having twenty nymphs in each jar, it devoured 12–16 nymphs in an hour which further confirmed its predatory role.

Ananthakrishnan<sup>1,2</sup> mentioned several insect-enemies of thrips but it seems to be a first record of *Polistes hebraeus* (Fabricius) being predaceous on *Rhipiphorothrips cruentatus* Hood feeding on roses.

The author is highly thankful to Dr. T. N. Ananthakrishnan, Entomology Research Unit, Loyola College, Madras-34, for the identification of the thrips.

***Sophora tomentosa* Linn.—A New Host for *Macrosiphum* (*Acyrtosiphon*) *gossypii* Mordv. (Homoptera: Aphididae)**

The aphid, *Macrosiphum* (*Acyrtosiphon*) *gossypii* Mordv. has been recorded on cotton and described its pest<sup>1</sup>. Two subspecies of this insect, *pactoskii* and *turanicum* were observed on stems of *Lepidium perfoliatum*<sup>1</sup> and cotton<sup>2</sup> respectively.

During March 1974, *Sophora tomentosa* Linn. a leguminous evergreen shrub cultivated in gardens around bungalows was found very severely infested with *M. (A.) gossypii* Mordv. in the nursery at Haryana Agricultural University, Hissar, India. Due to damage done by this aphid the growth of the plant was very much retarded. So far cotton and *Lepidium perfoliatum* are the only recorded hosts of this aphid. Hence, *S. tomentosa* Linn. is a new host for *M. (A.) gossypii* Mordv.

Sincere thanks are due to Dr. T. P. Yadava for providing facilities and to Dr. S. Kanakaraj David for identifying the insect.

## REVIEWS AND NOTICES OF BOOKS

### Absorption Spectroscopy of Organic Molecules.

By V. M. Parikh. (Addison-Wesley Pub. Co., Reading, Massachusetts 01867, U.S.A.), 1974. Pp. x + 325. Price not given.

The book is intended mainly to undergraduate students of different disciplines who want to get initiated into spectroscopy. Accordingly, the author begins with a quick review of basic physics in Chapter 1. The book covers in Chapters 2, 3, 4 and 5 in considerable detail the fields of uv, ir, n.m.r. and mass spectrometry. Basic principles of each technique instrumentation, interpretations of spectra and applications are discussed in each chapter. Chapter 6 is devoted to the integration of various techniques. The author has given many spectroscopic problems. Researchers and practising chemists may find the book useful as a source of quick reference (covered upto 1971 only). The author has included extensive charts of spectroscopic correlation in the appendix, again useful to practising chemists.

The get-up of the book is excellent and appealing, and it is free from typographical errors.

T. R. KASTURI.

### Chemistry : A Unified Approach (3rd Edition).

J. W. Buttle, D. T. Daniels and P. J. Beckett. (Butterworths, London, WC. 2 B4 AB), 1974. Pp. x + 580. Price £2.95.

The book as the authors have pointed out may be divided broadly into three parts. The first part from chapters one to seven deals with the Physical aspects of chemistry such as the development of the structure of the atom, the concept of atomic orbitals, nature of the chemical bond, properties of the different states of matter, properties of solutions, thermochemical concepts, reaction rates, chemical equilibria, redox potentials and other related concepts relevant to the understanding of the behaviour of chemical elements and their compounds.

The second part from chapters eight to seventeen discusses the origin and distribution of the elements in the earth, their extraction from the ores, the properties and commercial applications of these elements and their compounds. That there is a theoretical basis for the properties exhibited by the elements as well as their compounds has been brought out throughout the discussion in an easily

understandable way. Special emphasis has rightly been given to the structural features of the elements and their compounds.

Chapters eighteen to twenty-six deal with the chemistry of organic compounds—their sources, reactions and applications. Throughout this discussion wherever possible an attempt has been made to educate the student on the probable reaction mechanism.

In addition to these three main divisions there is a brief but useful discussion of the modern experimental methods in chapter twenty-seven and an excellent introduction to "the aspects of chemical industry" in chapter twenty-eight. At the end of each chapter a number of questions are given which the student may profitably attempt to solve and thus enhance his understanding of the subject. Answers to several numerical problems are also given at the end of the book. Throughout the book the subject-matter has been kept lively and interesting and the approach has been completely modern.

The very fact that the book has gone into its third edition within a short period of eight years is a measure of its success. The authors have intended the book for students taking the pre-degree and general degree courses in Great Britain. It could certainly be recommended for students taking the degree courses of Indian Universities. Though it may not give all the information that an undergraduate of an Indian University requires to face his examination, it certainly excels other books of comparable standard in several respects and has information and ideas that every undergraduate student of chemistry ought to know.

G. K. NARAYANA REDDY.

### Books Received

*Solid State Chemistry*. Edited by C. N. R. Rao. (Marcel Dekker, Inc., 305 E. 45th St., New York, N.Y. 10017), 1974. Pp. x + 918. Price \$59.50.

*Advanced Soil Physics*. Edited by C. Dakshinamurti. (Indian Council of Agricultural Research, New Delhi-1), 1972. Pp. x + 249. Price Rs. 15.00.

## CURRENT SCIENCE

*Fortnightly Journal of Research*

Issued on the 5th and 20th of each month

### IMPORTANT NOTICE TO SUBSCRIBERS OF THE JOURNAL

As you are aware CURRENT SCIENCE has been coming out regularly on the due dates as above with the kind co-operation of you all.

On account of the sharp increase in the cost of quality paper used for the Journal, increase in rates of block making materials, increase in postal rates and the increase in the establishment charges it has become impossible for the Association to issue the Journal, unless the subscription rates are put up.

The Working Committee of the Association has reluctantly decided at its last meeting, to enhance the subscription of CURRENT SCIENCE with effect from 1st January 1975 for institutions :

India Rs. 84 - Foreign Rs. 150.00 \$ 20.00 or £ 8.0.0

The subscription rates for individual subscribers however will remain the same as now.

The continued co-operation of our subscribers is requested.

Bangalore-6  
30th July 1974

## INFORMATION TO CONTRIBUTORS

CURRENT SCIENCE is the Premier Science Fortnightly of India published by the Current Science Association, Bangalore and issued on the 5th and 20th of each month. All material intended for publication in CURRENT SCIENCE and books for review should be addressed to the Editor, *Current Science*, Raman Research Institute, Bangalore-560006.

The following types of Scientific Communications will be considered for publication :

- (i) Review articles on topics of major current interest not exceeding 4,000 words;
- (ii) Original Research Papers—not exceeding 2,000 words;
- (iii) Letters: These are brief reports of research of unusual and wide interest—they should not exceed 700 words in general;
- (iv) Short Scientific Notes—not exceeding 250 words.

Articles and papers should include a short abstract at the beginning.

References are indicated by superscripts in the text. The style of references should be *Journal*: The names of the authors, the journal, year, volume and page.

*Book*: Authors names, the title of the book, name and location of the publishers, year and page.

"Personal Communications" and "Unpublished Work" do not go into references and should be incorporated in the text. Acknowledgements should be brief.

Statements that the work is contribution No..... of the Institute, declarations that the Director has authorised publications, etc., are not printed.

"Series" papers are discouraged.

Manuscripts, to be submitted in duplicate, should be typewritten in double space on one side of the paper, carefully revised and in final form for printing. Illustrations should be minimum in number, drawn in black and white with Indian ink on bristol board. Figures are usually reduced to one column width, and the originals should be about twice their final size.

No reprints are supplied gratis, but can be had on request at cost per V.P.P.

Business correspondence, remittances, subscriptions, advertisements, reprints, exchange journals, etc., should be addressed to the Manager, Current Science Association, Raman Research Institute, Bangalore-560006.

# MANGANOAN CUMMINGTONITE FROM SAKARSANAHALLI, KOLAR DISTRICT

G. V. ANANTHA IYER AND T. R. NARAYANAN KUTTY

Department of Inorganic and Physical Chemistry, Indian Institute of Science, Bangalore 560 012

## ABSTRACT

Manganoan cummingtonite from the carbonate horizons of Sakarsanahalli is unique in containing  $2.45 \text{ Mn}^{2+}$  per formula unit. The manganese content of this mineral is the highest that has been reported so far. It has a  $\text{Mg}:\text{Mn}:\text{Fe}$  ratio of  $49:42:9$ . The unit cell dimensions are  $a = 9.598 \text{ \AA}$ ,  $b = 18.072 \text{ \AA}$ ,  $c = 5.266 \text{ \AA}$ ,  $\beta = 103^\circ 44'$ . The  $\beta$ -angle corresponds to a value between that of tremolite and cummingtonite, with a smaller  $c$ -value. This can only be attributed to the enrichment of  $\text{Mn}^{2+}$  in the  $\text{M}_4$  site with a possible 8-coordination as against the normal 6-coordination.

It is generally believed that manganese content in the monoclinic iron-magnesium amphiboles  $(\text{Mg}, \text{Fe})_7\text{Si}_8\text{O}_{22}(\text{OH})_2$  (cummingtonite-grunerite series) will not exceed 2 atoms per formula. This originates from the expectation that the larger divalent cations preferentially occupy the  $\text{M}_4$  sites in the crystal structure, whereas the smaller cations fill in the various  $\text{Y}(\text{M}_1, \text{M}_2, \text{M}_3)$  positions, all the sites having distorted octahedral coordination<sup>1</sup>. Contrary to this view, a unique amphibole containing  $2.45$  atoms per formula ( $20.0\%$  by wt.  $\text{MnO}$ ) has been collected from Sakarsanahalli, Kolar District (Lat.  $12^\circ 48'$ ; Long.  $78^\circ 13'$ ). The amphibole occurs in the metamorphosed "silicate-carbonate" horizon of an abandoned manganiferous limestone quarry, west of the village. The quarry is a part of the complex rock exposures occurring as isolated small rises within the granites and gneisses of the south-west margin of Kolar Schist belt. The chief rock types of the complex are: carbonates ( $\text{Mn}$  — calcite +  $\text{Mn}$  — dolomite + amphiboles), ferruginous schists (quartz + haematite + magnetite + anthophyllite + talc), metapelites (cordierite + sillimanite + muscovite + quartz), pyroxenites (diopside + garnet + calcic amphiboles + clinozoisite + quartz) and amphibolites (hornblende + plagioclase + quartz). Manganese is a common substituent to varying degree in pyroxenes, garnets, and amphiboles. Tremolite and cummingtonite are the normal constituents of the carbonate rock.

Manganoan cummingtonite occurs as tufted acicular fibres along the localised shear planes in the carbonate rocks. The fibres could easily be handpicked and the sample thus obtained is treated with dilute hydrochloric acid. Microscopic examination reveals that the phase purity is over  $99\%$ . The amphibole is pale glistening white to light brown in colour. Most of the crystals are in the form of fine fibres (asbestiform). However, long slender transparent crystals can often be seen which show acicular and prismatic habits (Fig. 1). They

are non-pleochroic and show lamellar twinning parallel to  $c$ -axis. The extinction angle varies from  $15^\circ$  to  $18^\circ$ . The biaxial needles are optically negative. The optical properties are given in Table I, which corresponds to the manganoan cummingtonite reported by Jaffe *et al.*<sup>2</sup>. Except by chemical means, it is often difficult to conclusively identify this mineral. It may be mistaken for tremolite asbestos which has optical properties similar to manganoan cummingtonite.

FIG. 1. Manganoan cummingtonite, Sakarsanahalli, Magnification,  $\times 25$ .

## CHEMISTRY

The carbonates, the cummingtonite and the coexisting tremolites are analysed by wet chemical methods. Cations are estimated complexometrically; water and carbon dioxide by gas effluent analysis. No fluorine is detected in the sample (Tables I and II). The analytical data show that the amphibole under consideration is manganoan cummingtonite with the formula  $(\text{Mg}_{2.9}\text{Mn}_{2.5}\text{Fe}^{2+}_{0.8}\text{Ca}_{0.3}\text{Al}_{0.3})\text{Si}_{7.99}\text{O}_{21.8}(\text{OH})_{2.1}$ . According to Jaffe *et al.*<sup>2</sup>, the monoclinic  $\text{Mg}$ – $\text{Mn}$ – $\text{Fe}$  amphibole containing 50 or above mole per cent  $\text{Mg}$  is to be called cummingtonite even though the manganese substituted mineral is optically negative. The  $\text{Mg}:\text{Mn}:\text{Fe}^{2+}$  is  $49:42:9$  for the present cum-

ingtonite. Manganese substituted cummingtonite-grunerites are known by names like tirodite<sup>3,4</sup> (5 to 10 wt% MnO and minimum FeO) and danne-morite<sup>5,6</sup> (7.4% MnO and 24 wt% FeO). Jaffe *et al.*<sup>2</sup> have reported a manganooan cummingtonite with 2.28 Mn<sup>2+</sup> per formula unit. This analysis is doubted because of the spessartite inclusion in the sample and that the analysis is carried out spectrographically. Klein<sup>7</sup> has analysed three cummingtonites containing 2.02, 1.74 and 1.63 atoms of Mn<sup>2+</sup> per formula. He has concluded that naturally occurring members of the cumming-tonite-grunerite series vary from 35–100 mole % of Fe<sub>7</sub>Si<sub>8</sub>O<sub>22</sub>(OH)<sub>2</sub> and 0–34 mole% of Mn<sub>7</sub>Si<sub>8</sub>O<sub>22</sub>(OH)<sub>2</sub> components. The composition of manganooan cummingtonite from Sakarsanahalli exceeds this limit for manganese. Al<sub>2</sub>O<sub>3</sub> and CaO contents in this amphibole are also more than the normal range encountered in cummingtonites. However, the Z-position is nearly filled by Si. The CaO content of 2.02 wt% (0.32 atoms per formula) indicates that Ca is more soluble in manganooan than Mn-poor cummingtonite.

The reason for such a higher concentration of manganese in this amphibole is the Mn-rich environment under which it is formed. This is indicated by the manganese content in the associated carbonates (Table II). They are, in general, (Ca, Mn, Mg) CO<sub>3</sub> with MnO content varying from 12 to 25 wt%, corresponding to manganooan calcite to kutnohorite compositions. This is further shown by the manganese content in the coexisting tremolite with 0.81 and 1.16 atoms per formula. In tremolites, Mn<sup>2+</sup> substitutes for Fe<sup>2+</sup> in the Y-positions since the bigger calcium ions occupy the M<sub>4</sub> sites.

## POWDER DIFFRACTION PATTERN

Powder diffraction pattern for the manganooan cummingtonite is obtained with a Philips camera of 114.6 mm diameter, using Cr K <sub>$\alpha$</sub>  radiation (V-filtered) from a Rich-Seifert X-ray unit. In order to obtain the weak reflections, the film is exposed for 48 hours. Measurements are made to an accuracy of 0.05 mm and the film shrinkage is found to be lower than this. The 0 12 0 reflection is used to get the *b* value while 310, 061 and 20 $\bar{2}$  reflections are used to extract *a* sin  $\beta$ , *c* sin  $\beta$ , and  $\beta$  values. This results in the following cell dimensions: *a* = 9.598 Å, *b* = 18.072 Å, *c* = 5.266 Å,  $\beta$  = 103° 44'. The cell volume is 887.2 Å<sup>3</sup> and a calculated density of 3.34 g/cc. The measured density is 3.26 g/cc. Using the cell parameters, the observed reflections in the powder diffraction pattern are indexed (Table III). The agreement between calculated and the observed *d*-spacing indicates the accuracy of the cell parameters.  $\beta$ -value is intermediate between cumming-

| 1.959           | 281   | 8         | 1.185           | 5 11 2 | 10        |

tonite ( $102^\circ$ ) and tremolite ( $105^\circ$ ). The smaller  $b$ - and  $c$ -values of the manganooan cummingtonite are nearer to that of tremolite. The  $a$ -axis, however, remains unchanged. The linear plots of  $a \sin \beta$  and of  $b$ -values against composition in the Fe-Mg series will not hold good for the Mg-Mn-Fe ternary cummingtonites. The intensity ratios of the observed reflections also are at variance from those of Mn-free cummingtonite.

#### DISCUSSION

In the silicate-carbonate horizons, tremolite and cummingtonite are formed by the reaction of manganooan dolomite with silica impurities during metamorphism as per the reactions:

The Ca/Mg+Mn+Fe ratio in the dolomite is more than that of tremolite and that of cummingtonite. Therefore manganooan calcite becomes a product. The coexisting carbonates have all the characteristics of high temperature variety and are crystalline. Cummingtonite and tremolite thus formed will incorporate considerable amounts of

manganese, the extent of which is limited by the crystal chemistry of the silicates.

In the amphibole structure, bigger Ca-ions occupy the  $M_4$  sites with an eight-coordination while the smaller cations show preference to  $M_1$ ,  $M_2$  and  $M_3$  sites which have distorted octahedral coordination. This results in the tremolite and hornblende structures<sup>8</sup>. On the other hand, in cummingtonite, all the four sites,  $M_1$  to  $M_4$  have distorted octahedral coordination. The dual coordination of  $M_4$  sites in clinoamphiboles is possible due to the noncoplanar configuration of the oxygens forming the bases in the silicate double chains. The  $(\text{Si}_4\text{O}_{11})$  chains can be bent about the (001) axis, modifying the nature of their stacking. Accordingly, the  $\beta$  adopts extreme values. The  $M_4$  sites can thus acquire any coordination between six and eight. In the Mg-Fe-Mn cummingtonite, containing more than two  $\text{Mn}^{2+}$  per formula, can have manganese filling in the  $M_1$  or  $M_3$  sites, over and above the  $M_4$  occupancy. In such cases,  $\text{Mn}^{2+}$  in the  $M_4$  site gains eight-coordination, with a higher ionic radius ( $1.01 \text{ \AA}$  for the high-spin state)<sup>9</sup>, the silicate chains suitably modify and the structure approaches that of tremolite. This accounts for the closer similarity in physical properties of manganooan cummingtonite and tremolite and so also the cell parameters. Besides, Ca has higher solubility in Mn-cummingtonite than in Mn-free variety which supports the above conclusion. However, due to crystal field effects, the solid solubility between Mn-cummingtonite and tremolite can be expected to be limited.

## DIMETHYL SULPHOXIDE COMPLEXES OF RARE-EARTH BROMIDES

P. V. SIVAPULLAIAH AND S. SOUNDARARAJAN

*Department of Inorganic and Physical Chemistry, Indian Institute of Science, Bangalore 560 012*

## ABSTRACT

Dimethyl sulphoxide (DMSO) complexes of six rare-earth bromides of the composition  $M(\text{DMSO})_8\text{Br}_2$ , where  $M = \text{La, Pr, Nd, Sm, Ho and Y}$  have been prepared and characterized. Infrared studies of the complexes indicate that dimethyl sulphoxide coordinates to metal through oxygen. Conductivity data show a coordination number of ten for all rare-earths. The relative effect of halide ions on the coordination number of the rare-earth ions is discussed.

## INTRODUCTION

**D**IMETHYL sulphoxide complexes of rare-earth chlorides<sup>1</sup>, nitrates<sup>2</sup> and perchlorates<sup>3</sup> have been reported from this laboratory. In all these cases a coordination number of eight for the lighter lanthanides and seven for the heavier lanthanides and yttrium has been suggested from the conductance data. But from the crystal and molecular structure studies of dimethyl sulphoxide complexes of lanthanum nitrate<sup>4</sup> and ytterbium nitrate<sup>5</sup>, it has been shown that the coordination numbers for lanthanum and ytterbium should be ten and nine respectively. Recently rare-earth iodide complexes of dimethyl sulphoxide have been prepared and characterized in this laboratory<sup>6</sup>. A coordination number of nine for all the rare-earths has been suggested in these complexes from the conductivity data. So far very little work has been carried out on the effect of the bromide ion on the coordination number of the rare-earths. In the present paper, for the first time, the isolation and characterization of rare-earth bromide complexes with dimethyl sulphoxide are described.

## EXPERIMENTAL

**Materials.**—The hydrated rare-earth bromides were prepared from pure (99.9%) rare-earth oxides and hydrobromic acid.

Water white DMSO (Crown Zellerbach Co., U.S.A.) was used for the preparation of the complexes.

The commercial dimethylformamide (DMF) was shaken with KOH pellets for two hours and distilled under reduced pressure. The middle fraction distilling at 70° C at 10 mm pressure was collected and its specific conductance was  $9.1 \times 10^{-7} \text{ ohm}^{-1} \text{ cm}^{-1}$  at 30° C.

Acetonitrile was purified by the standard method<sup>7</sup>. Its specific conductance was  $2.63 \times 10^{-6} \text{ ohm}^{-1} \text{ cm}^{-1}$ .

**Preparation of the Complexes.**—One gm. of the hydrated bromide was dissolved in 2 ml of DMSO and the excess of the ligand was removed under reduced pressure. The solid crystalline product

was washed with dry benzene to free it from DMSO and dried.

**Analyses.**—The complexes were analysed for their metal, bromide and DMSO parts. The metal content was estimated by EDTA titrations using xylenol orange as the indicator<sup>8</sup>. The bromide was estimated by Volhard's method and the DMSO by oxidation with excess of permanganate<sup>9</sup>. Since bromide is also oxidised by permanganate, it was removed as silver bromide by adding silver nitrate.

**Infrared Spectra.**—The infrared spectra of the complexes were taken in both nujol mulls and KBr pellets employing a Carl Zeiss UR-10 infrared spectrophotometer. The mull and KBr pellet spectra of the complexes were almost identical. The important absorption bands in the region 3600–600  $\text{cm}^{-1}$  and their assignments, similar to those given for other lanthanide-DMSO complexes, are presented in Table II.

**Conductivity Measurements.**—The molar conductances of the complexes in acetonitrile, dimethylformamide and water were determined with a Siemens conductivity bridge using an immersion cell (Cell constant 0.665). The concentration of the solutions was ca. 0.001 M.

**Molecular Weight Measurements.**—The molecular weights for some representative complexes in water were determined by the freezing point depression method. However, molecular weight measurements could not be carried out in organic solvents because of their poor solubility in suitable solvents. Molecular weight and conductance data are presented in Table III.

## RESULTS AND DISCUSSION

Analytical results (Table I) show that the complexes have the formula  $M(\text{DMSO})_8\text{Br}_2$  where  $M = \text{rare-earth metal}$ . Unlike the corresponding perchlorate complexes, the metal : ligand ratio is eight for all the lanthanides and yttrium. However, the composition is similar to that of the iodide complexes.

The complexes are very hygroscopic, insoluble in non-polar solvents and acetone, and soluble in

\* Spectrum of DMSO was taken in the liquid phase. Spectra of the complexes taken in nujol mulls are presented.

Abbreviations: vs = very strong; s = strong; m = medium; w = weak.

polar solvents. The colours of the complexes are similar to those of the corresponding salts.

The molar conductances of the complexes in water and DMF are in good agreement with those reported for 1:3 and 1:2 electrolytes respectively<sup>10,11</sup>. The molar conductances in acetonitrile, however, show that the complexes behave as 1:1 electrolytes<sup>11</sup> which suggest the possibility of two of the bromide ions being coordinated to the rare-earth ions. Thus a coordination number of ten can be postulated for all the rare-earth ions. This is the only example where a coordination number of

ten is suggested for a heavier lanthanide and yttrium in DMSO complexes, whereas for lighter lanthanides and coordination number of 10 has been postulated in rare-earth nitrate-DMSO complexes from crystal structure studies<sup>4</sup>.

The molecular weight data for the complexes in water show the presence of twelve species thereby suggesting the complete dissociation of the complexes in water.

The infrared spectra of all the complexes are similar showing no significant dependence on the central metal ion. The intense band occurring at

1045 cm<sup>-1</sup> attributable to the S=O stretch<sup>12</sup> in free DMSO shifts to about 1016 cm<sup>-1</sup> in the complexes, demonstrating the involvement of oxygen in the coordination. An enhancement in the C-S stretching fundamental (from 695 cm<sup>-1</sup> to about 718 cm<sup>-1</sup>) further confirms the oxygen coordination<sup>1</sup>. Absence of a band at 1045 cm<sup>-1</sup> indicates that no occluded or lattice held ligand is present in the complexes.

The extent of S=O shift, which is a measure of the metal-oxygen bond strength in the complexes, is less in bromide complexes (ca. 30 cm<sup>-1</sup>) than in the corresponding rare-earth perchlorate complexes of DMSO (ca. 50 cm<sup>-1</sup>)<sup>3</sup>. These shifts in the rare-earth chloride, bromide and iodide complexes (ca. 35, 30 and 25 cm<sup>-1</sup>) indicate that the metal-oxygen bond strength decreases as we go from chloride to iodide complexes. From the data obtained, the rare-earth bromide-DMSO complexes may be represented as [M(DMSO)<sub>8</sub>Br<sub>2</sub>]<sup>+</sup>Br<sup>-</sup>.

As pointed out in literature<sup>13</sup>, the number of ligands coordinated to the metal ion is dependent upon the anion in the complex. In the case of rare-earth chloride-DMSO complexes the maximum number of ligands coordinated to the metal ion is four, while in the case of the bromide complexes it is eight. In the rare-earth iodide complexes, however, the number of DMSO molecules coordinated to the metal ion remains eight as in the case of bromide complexes.

For the lanthanide ions, the coordination affinities of halide ions lie in the sequence F<sup>-</sup> > Cl<sup>-</sup> > Br<sup>-</sup> > I<sup>-</sup><sup>14</sup>. Hence it is to be expected that rare-earths will add on more number of ligands in bromide complexes than in chloride ones. However, in the case of iodide complexes the number of ligands coordinated

to the metal ion is not further enhanced, probably due to the large ionic size of iodide ion. The interesting feature of the bromide complexes is that the lanthanides have a higher coordination number, as the number of anions coordinated to the metal ion is two (compared to one in the case of the iodide complexes) and the number of ligands coordinated is also the maximum.

## A CONTRIBUTION TO THE EMBRYOLOGY OF *UTRICULARIA SCANDENS* OLIVER

G. SHIVARAMIAH, S. SUNDARA RAJAN AND K. SANKARA RAO

Department of Botany, St. Joseph's College, Bangalore 560 001, India

CONSIDERABLE amount of work has been done on the embryology of the genus *Utricularia*<sup>1-7</sup>. The genus *Utricularia* exhibits some interesting features embryologically. The notable among them are the endosperm haustoria and the undifferentiated embryo.

The present account deals with the embryology of *Utricularia scandens* Oliver. The plant is a minute twiner. It is often found growing in association with *Utricularia wallichiana*. The material for present investigation was collected near Hassan (Karnataka State). Flowers and fruits were fixed in F.A.A. After dehydration and paraffin embedding sections were cut at 10–12  $\mu$  and stained with Heidenhein's haematoxylin and eosin.

The flowers are very small, blue in colour, borne on slender scapes. Seeds are minute, reticulate and scrobiculate.

The ovules are anatropous, unitegmic and tenuinucellate. Occasional hemianatropous ovules have been noticed. Placental nutritive tissue is seen at the micropylar part of the ovule (Fig. 11 at corner). A hypodermal archesporial cell arises when the ovule is still erect (Fig. 1). In about 3% of the ovules three archesporial cells have been noticed (Fig. 2). Multiple archesporium is reported earlier in *Utricularia flexuosa* and *Utricularia reticulata*<sup>4-5</sup>. The archesporial cell directly develops into the megaspore mother cell (Fig. 3). In no case more than one megaspore mother cell has been observed. The megaspore mother cell undergoes reduction division and forms a linear tetrad of megaspores (Figs. 5–7). Usually the chalazal megaspore alone is functional and the rest degenerate. But in some ovules two megaspores, i.e., the chalazal two show signs of development (Fig. 4). The functional megaspore divides thrice and develops into an eight-nucleate embryo sac of the Polygonum type (Figs. 8–12). The organised embryo sac is seven-celled (Fig. 12). The embryo sac is extra-ovular. The antipodals are three in number and are organised as cells. The endothelium does not cover the embryo sac completely. It is restricted only to the central region of the embryo sac. Fertilization is porogamous. The first division of the primary endosperm nucleus is transverse to the

long axis of the embryo sac (Fig. 13) and it is followed by the formation of a wall (Fig. 14). The endosperm is *ab initio* cellular. The chalazal cell divides first. The plane of division may be transverse (Fig. 17) or longitudinal (Fig. 16). While this is the usual pattern of division during early endosperm development, interesting variations are observed in some ovules. In some cases, the primary endosperm nucleus divides twice to form four superposed endosperm cells (Fig. 18). In such ovules the middle two cells develop into endosperm proper while the micropylar and chalazal cells develop into haustoria. In very few instances the chalazal endosperm cell becomes coenocytic with a varying number of nuclei (four or five) (Figs. 19–21). The chalazal and micropylar parts of the endosperm develop into haustoria while the middle part develops into endosperm proper. The endosperm haustoria are exactly similar to those of *U. caerulea*<sup>3</sup> (Fig. 22).

The zygote divides only after the initial development of haustoria. The first division of the zygote is transverse (Figs. 23 and 24) resulting in the formation of two superposed cells *ca* and *cb*. Both the cells divide transversely and form a linear pro-embryo of four cells—*l*, *l'* and *ci* and *m* (Fig. 25). *ci* divides once and forms a suspensor of two cells (Fig. 26). The other three cells undergo further divisions and contribute to the embryo proper. The sequence of divisions in the embryogeny follows the Solanad type. The mature embryo is undifferentiated and similar to that seen in *U. caerulea*<sup>3</sup>.

Our thanks are due to the Principal, St. Joseph's College, Bangalore, for facilities.

## LETTERS TO THE EDITOR

### A NOTE ON SUDDEN FIELD ANOMALY PATTERNS (SFA)

ONE of the sudden ionospheric disturbances (SID's) in the sunlit hemisphere, due to the interaction of solar flare produced radiation with the earth's upper atmosphere, is the perturbation in LF field strength (monitored over long paths) designated as Sudden Field Anomaly (SFA). The potentiality of recording the field strength of LF transmissions propagated over long paths as a simple method for solar flare petrol was suggested by Lauter and Sprenger (1958). Experimental investigations of Nestorov (1962), Shirke and Alurkar (1963) and Mitra (1959, 1964) using 164 KHz transmissions from Allouis and Tashkent stations respectively demonstrated this possibility. It is now considered that the LF field strength observation (SFA) is the most efficient method for monitoring and interpreting solar flare effects in the lower ionosphere (Ohle *et al.*, 1974).

Subrahmanyam, Sastri and Deshpande (1974) recently reported the varied nature of the solar flare effect on LF field strength over the Tashkent-Delhi path (path length is about 1600 km) and observed six distinct types of SFA patterns, a typical example of which, with their average size and time structure is shown in Fig. 1. It can be seen that the six SFA patterns can be classified into two categories: Simple and Complex. The

simple SFA patterns are Type II and IV wherein the signal strength either increases (Type II) or decreases (Type IV) following the flare and recovers to the normal level. The complex SFA patterns are Type I, Ia, Ib, and III wherein the signal strength undergoes a series of increases and decreases. The SFA patterns are noticed to exhibit seasonal trends in that Type IV and Ia SFA patterns which are essentially attenuation effects of solar flare, on LF field strength occur mostly in winter and autumn and more or less absent in summer while Type II SFA pattern which is an enhancement effect of solar flare on LF field strength occurs mostly in summer and spring months. One of the interesting characteristics of SFA patterns is that the total duration of simple SFA patterns (Type II and IV) is much less than that of complex patterns (Type I, Ia and III): in fact, the ratio of the latter to the former is of the order of two. This feature can clearly be seen from Fig. 1.

This brief communication is devoted to an understanding of the characteristics of SFA patterns mentioned above, *i.e.*, the slow and relatively gradual recovery nature of field strength in complex patterns compared to simple patterns. The interpretation advanced is that the recovery nature is mainly governed by the range of heights over which the excess flare induced ionization is produced due to X-ray flux enhancement in the 1–20 Å band. Following this argument, the Type II and IV SFA patterns may be understood as due to extra ionization at heights below 60 km and above 75 km respectively [as a result of hardening of the X-ray spectrum (1–20 Å) and soft X-ray flux (1–20 Å) enhancement respectively] whereas the complex SFA patterns (Type I, Ia, III) are due to excess ionization in the height range 60–70 km. Then the recovery nature in complex SFA patterns is governed by the negative ion chemistry of the D-region and the slow recovery nature of the field strength could be due to the slow release of electrons from negative ions by photo-detachment. Support for this interpretation comes from the recent work of Thomas *et al.* (1973), who have studied the role of negative ion changes in the D-region during flare conditions. Using a simulation procedure, with the proportional change in ion pair production rate at each height, represented by an analytical expression (representative of flare effect), with a rise time of 5 min and an

FIG. 1. Typical SFA patterns with their average size and time structure, observed over Tashkent-Delhi path.

exponential decay with a time constant of 5 min they have calculated the variations in concentrations of electrons and negative ions ( $O_2^-$ ,  $NO_3^-$ ,  $CO_3^-$ ) at different heights for two cases: without and with the photo-detachment of electrons from negative ions ( $NO_3^-$ ,  $NO_2^-$ ,  $CO_3^-$ ). They observed that if photo-detachment of electrons from negative ions is taken into consideration, the recovery of electron concentration after its maximum is considerably slowed down and this feature is most striking at a height of 64 km. This can be seen from Fig. 2 reproduced from the paper of Thomas *et al.* (1973).

FIG. 2: The proportional change in ion pair production rate at all heights during a flare and the resulting variations of electron concentrations computed for 80, 72, and 64 km in the presence of photodetachment of electrons from ions  $CO_3^-$ ,  $NO_3^-$ ,  $NO_2^-$  according to the rates shown in Table I of Thomas *et al.* (1973) (after Thomas *et al.*, 1973).

It is to be emphasized however that the work of Thomas *et al.* (1973) is based on the assumption that the proportional change in ion pair production rate is the same throughout the D-region, which is an idealised condition. Further work is therefore necessary for a better understanding of the influence of negative ion changes on the recovery

nature of field strength in complex SFA patterns by analysing specific events with the help of X-ray flux data, now available from SOI-RAD satellite.

#### ANTIBACTERIAL ACTIVITY OF BIS-*s*-TRIAZINYLAMINOPHENYLSULPHONE

SEVERAL derivatives and analogues of amino sulphones have been shown to have strong tuberculostatic<sup>1</sup>, antileprotic<sup>2</sup> anticonvulsant action and to be of potential use therapeutically. *s*-Triazine nucleus has also been the subject of several investigators in the realm of potential therapeutic agents for diseases like malaria and cancer. Foye and Buckpitt<sup>3</sup> carried out the condensation of cyanuric chloride with diamino thiazolylphenylsulphone in different proportion in order to prepare products of therapeutic use.

We have prepared Bis-*s*-Triazinylaminophenylsulphones of the type (I) with a view to testing them as therapeutic agents.

where  $R_1$  and/or  $R_2$  = chloro, phenylamino, substituted phenylamino.

4-4'-Diaminodiphenylsulphone was condensed with cyanuric chloride at 0° to get *p, p'*-[Bis (2, 4-dichloro-*s*-triazin-6-yl-amino)] diphenyl sulphone which was then condensed with different bases (one mole as well as two moles), *e.g.*, Aniline, *o*-, *m*- and *p*-toluidine at 30–35° and 80–90° respectively using acetone or dioxane as solvent,

### Antibacterial Testing

The following strains were used for testing the antibacterial activity employing agar slants<sup>4</sup>:

A Gram-positive bacterial strains like *Bacillus megaterium*, *Bacillus citreus*, *Bacillus subtilis*, *Staphylococcus aureus*.

B. Gram-negative bacterial strains like *Escherichia coli*, *Aerobacter aerogenes*, *Salmonetta typhi*, *Salmonella paratyphi* A., *Salmonella paratyphi* B., *Shigella dysenteriae sonnei*, *Sh. dy. Shiga*, *Sh. dy. flexneri*, *Sh. dy. schimitazii*, *Pseudomonas aeruginosa*.

Testing was done in nutrient broth. After inoculation with a loopful of culture from the slant, the seeded nutrient broths were incubated at 37° C for 24 hours. The various dilutions of the sulphone derivatives were prepared with a slight modified method as proposed by Dhar *et al.*<sup>5</sup>.

The sulphone derivatives were dissolved in alcohol/acetone to obtain a 10 mg/ml solution. From this solution 0.2 ml was added to 1.8 ml of the above seeded broth which formed the first dilution and contained one mg of sulphone per ml of the seeded broth. One ml of the first dilution was further diluted with one ml of seeded broth to produce the second dilution and so on till five such dilutions were obtained.

From the experiment, it was observed that all the above derivatives are able to inhibit the growth of all Gram-positive bacteria at the 250 µg/ml concentration and all Gram-negative bacteria at the 500 µg/ml concentration.

### Experimental

(a) Preparation of *p-p'* [Bis(2, 4-Dichloro-*s*-triazin-6-yl-amino)]-diphenylsulphone.—4-4'-Diaminodiphenylsulphone (0.01 mole) dissolved in acetone (40 ml) was added to a solution of cyanuric chloride (0.02 mole) in acetone (40 ml) at 0°. Contents were stirred for an hour by simultaneous addition of aqueous sodium hydroxide solution (10 ml, 4%) and diluted with ice water (100 ml). The product was isolated and crystallised. Yield 84.5%, m.p. 360°.

(b) Preparation of *p-p'* [Bis(2-Arylamino-4-chloro-*s*-triazin-6-yl-amino)]-diphenylsulphone.—Bose (0.02 mole) dissolved in dioxane (10 ml) was added to the suspension of *p-p'* [Bis (2, 4-dichloro-*s*-triazin-6-yl-amino)] diphenyl sulphone (0.01 mole) in dioxane (60 ml) at 30–35°. A clear solution was obtained after an hour. Contents were stirred for an hour with the gradual addition of aqueous sodium hydroxide solution (10 ml, 4%) and diluted with ice water (100 ml). The product was isolated and crystallised. The products are as follows. % Yield and m.p. of Anilino : 86.2, 310° (d), *o*-toluidino : 73, 360°, *m*-toluidino : 70, 360° and *p*-toluidino : 72.12, 280°.

(c) Preparation of *p-p'* [Bis (2-4-Diarylamino-*s*-triazin-6-yl-amino)] diphenylsulphone.—Bose (0.02 mole) dissolved in dioxane (10 ml) was added to *p-p'* [Bis (2-Arylamino-4-chloro-*s*-triazin-6-yl-amino)] diphenylsulphone (0.01 mole) dissolved in dioxane (40 ml) and reflux in water bath at 80–85°, for 1½ hour with the simultaneous addition of aqueous sodium solution (10 ml, 4%). Contents were poured into crushed ice (100 g). The product was isolated and crystallised. % Yield and m.p. are as follows : Anilino : 84.00, 290 (d), *o*-toluidino : 69.10, 310°, *m*-toluidino : 73.00, 360°, *p*-toluidino : 77.33, 360°.

Authors are thankful to Prof. K. A. Thaker for providing research facilities. Shri K. S. Patel is also thankful to authorities of Saurashtra University for financial support.

### PSEUDOHALIDE COMPLEXES OF BISCYCLOPENTADIENYL MOLYBDENUM (VI)

BISCYCLOPENTADIENYL molybdenum (VI) oxydichloride and bisindenyl molybdenum (VI) oxydichloride have already been prepared by treating molybdenum (VI) oxytetrachloride with sodium cyclopentadienide and sodium indenide in tetrahydrofuran<sup>1</sup>. There is no reference in literature regarding the preparation or characterisation of pseudohalide complexes of biscyclopentadienyl molybdenum (VI) and bisindenyl molybdenum (VI) although the preparation and characterisation of metallocene pseudohalide complexes of titanium (IV), titanium (III), zirconium (IV), vanadium (IV) and thallium (III) have been reported<sup>2-8</sup>. Turco and Pecile<sup>10</sup>, Thayer and West<sup>11</sup> and Burmeister<sup>12</sup> have also studied the mode of bonding in certain metal-pseudohalide complexes.

The present communication deals with the preparation and characterisation of pseudohalide complexes of biscyclopentadienyl molybdenum (VI) by the interaction of biscyclopentadienyl molybdenum (VI) oxydichloride with potassium or sodium salts

of pseudohalides in tetrahydrofuran. The products were isolated by removing the solvent under reduced pressure and subsequent crystallisation from petroleum ether.

where R may be CN, NCO, NCS and N<sub>3</sub>  
and k is either potassium or sodium.

The compounds prepared vary from red brown to dark brown in colour and are stable in dry atmosphere. These compounds are non-volatile, soluble in common organic solvents and are hydrolysed by water, dilute acids and alkalis.

**Experimental.**—All the reactions were carried out in dry inert atmosphere. The solvents were dried and purified before use by conventional methods. Tetrahydrofuran was refluxed over potassium hydroxide followed by distillation in presence of lithium aluminium hydride.

To biscyclopentadienyl molybdenum (VI) oxydichloride 1.1 g (0.0035 mole) in tetrahydrofuran (100 ml) was added anhydrous potassium thiocyanate 0.058 g (0.0052 mole). The mixture was refluxed at 70–80° C for 2 hours, cooled and filtered. The filtrate on evaporation under reduced pressure gave red brown residue which on repeated crystallisation from petroleum ether (60–80° C) gave red brown crystals of  $(C_5H_5)_2 MoO(NCS)_2$  yield—80%. Anal. calcd. for  $(C_5H_5)_2 MoO(NCS)_2$ : C, 40.22; H, 2.79; Mo, 26.81%. Found: C, 40.12; H, 2.61; Mo, 26.60%.

Molybdenum was estimated as oxinate and C, H were estimated by microanalytical methods. The i.r. spectra of the compounds recorded on Perkin-Elmer Model-137 Spectrophotometer in KBr medium showed the following absorption peaks:

3010 2050 1710 1540 1470 1160 1050 955 850  
(m) (vs) (m) (w) (m) (w) (m) (m) (s)  
where vs = very strong; s = strong; m = medium;  
w = weak.

The i.r. spectrum of biscyclopentadienyl molybdenum (VI) oxydithiocyanate shows the usual peaks of  $C_5H_5^-$  group, viz., the frequencies at 3010 cm<sup>-1</sup> (C–H stretching), at 1470 cm<sup>-1</sup> (C–C stretching), at 1160, 1050 cm<sup>-1</sup> (C–H in plane bending) and at 850 cm<sup>-1</sup> (C–H out of plane bending). The peak at 960–45 cm<sup>-1</sup> is due to metal-oxygen, i.e., M=O linkage.

Metal thiocyanates (M–SCN) are indicated by C–N stretching vibration appearing at  $\geq 2100$  cm<sup>-1</sup> and C–S stretching vibrations at 690–720 cm<sup>-1</sup>. The metal isothiocyanates (M–NCS) are indicated by C–N stretching at  $\leq 2100$  and C–S stretching at higher frequency 780–860 cm<sup>-1</sup><sup>10</sup>. In cyclopentadienyl compounds, the later band 780–860 cm<sup>-1</sup>

may be masked by the strong absorption around 850 cm<sup>-1</sup> due to C–H out of plane bending vibrations of the ring. However, the absence of any bands in the region 650–750 cm<sup>-1</sup> and the presence of strong bands at 850 cm<sup>-1</sup> and 2050 cm<sup>-1</sup> strongly indicates the presence of M–NCS bonding structure. This is in accord with the observations of Burmeister<sup>12</sup> that N coordination usually results in an increase in C–S and C–N stretching values relative to free ion values (~ 749 cm<sup>-1</sup> and 2060 cm<sup>-1</sup>).

Similar observations were made in i.r. spectra of the metal cyanate showing an intense band at 1320 cm<sup>-1</sup> and this is consistent with the isocyanate structure<sup>11</sup>, i.e., M–NCO. Other pseudohalide complexes were prepared similarly and their analytical and i.r. data was in agreement with the calculated values.

#### CHEMICAL INVESTIGATION OF THE ESSENTIAL OIL OF PSEUDO- SORGHUM GRASS

THE essential oil (34 g) was separated into acidic and neutral part by treating with an aq. sodium hydroxide solution (5%). Acidic portion was found to contain two components, one giving positive ferric chloride colour test while the other giving effervescence with sodium bicarbonate solution. Therefore, acidic portion was taken in ether and washed with saturated solution of sodium bicarbonate. The sodium bicarbonate insoluble part yielded the solid phenol, i.e., xanthoxylene<sup>2-5</sup> (1.6 g) which was further confirmed by the preparation of its acetyl derivative and the soluble part yielded an

acid, i.e., 3-hydroxy-*p*-toluic acid<sup>6,7</sup> (0.47 g); this too was further confirmed by the preparation of its acetyl derivative.

The neutral part (32 g) was chromatographed over neutral alumina grade II and three fractions were collected by eluting the column with petroleum ether, benzene and ether.

**Petroleum ether fraction:** (TLC five spots) of alumina on extensive chromatography over silicagel and silicagel impregnated with silver nitrate (15%) afforded *n*-tridecane<sup>8,9</sup> (3.5 g), decanone-4<sup>9,10</sup> (0.86 g) and octanone-3 (0.53 g)<sup>11</sup>. All the three compounds have been identified on the basis of their physical, chemical and spectral data.

**Benzene fraction** (TLC, three spots): On extensive chromatography over active silicagel afforded two components, an aromatic ether (under investigation) and an ester, *p*-methoxy methyl cinnamate<sup>12,13</sup>, m.p. 87–88°.

**Ether fraction** (TLC, three spots): On extensive chromatography over active silica gel, afforded an open chain alcohol decanol-4. The structure has been confirmed on the basis of its physical, chemical and spectral data.

## CHEMICAL EXAMINATION OF THE FLOWERS OF *PEDALIMUM MUREX*

*Pedaliium murex* (Pedaliaceae) is a small flowering plant growing abundantly in the coastal regions of South India. Though there are reports<sup>1</sup> about its therapeutic uses, no detailed examination of the plant as a drug has been done so far. The leaves of this plant have been shown to contain flavonoid compounds<sup>2</sup>. We have now examined the polyphenolic components of the flowers of this plant and report the results in this communication.

The fresh flowers, collected around Madurai University area, were repeatedly extracted with 95% ethanol, till the extract was colourless. The combined extract after concentration was fractionated using neutral and basic lead acetate. The lead salt from the neutral lead acetate fraction after decomposition with hydrogen sulphide yielded a crude mixture of flavonoid compounds.

**Aglycones:** The residue from the decomposition of the neutral lead salt fraction was macerated repeatedly with ether to remove free aglycones and the ether extract after evaporation yielded a mixture of aglycones. Paper chromatography of the aglycone mixture using the B.A.W. as the solvent system (4:1:5, v/v) showed the presence of two flavonoids having  $R_f$  values 0.95 and 0.64. These were separated by preparative paper chromatography. The aglycone having the higher  $R_f$  value was found to be dinatin (5,7,4'-trihydroxy-6-methoxyflavone) by a detailed study of its U.V. spectrum and comparison with an authentic sample. The compound with lower  $R_f$  value was also studied in the same way and identified as quercetin (3,5,7,3',4'-pentahydroxyflavone).

**Glycosides:** The glycoside mixture obtained as the ether insoluble fraction was found by paper chromatography (B.A.W., 4:1:5, v/v) to be a mixture of two compounds ( $R_f$  values 0.32 and 0.28). These were separated by preparative paper chromatography using the same solvent system. The glycoside ( $R_f$  value 0.32) on hydrolysis with 7% sulphuric acid yielded glucose and quercetin (identified by paper chromatography). A detailed study of the U.V. spectra of the glycoside and the aglycone with and without the addition of the various shift reagents suggested its identity as quercetin-7-glucoside. Rigorous comparison of the natural material with authentic quercimeritrin confirmed the identity. The slow-moving component of the glycoside mixture ( $R_f$  value 0.28) on hydrolysis with 7% sulphuric acid yielded rhamnose in addition to quercetin and glucose. By a careful study of the U.V. spectra of the glycoside and aglycone with and without the addition of various reagents such as sodium acetate, sodium ethoxide,

boric acid and aluminium chloride. it was concluded that both the sugar residues are attached to the oxygen atom at the 7-position of the aglycone.

Further study concerning the sequence of attachment of the sugars and also the identification whether it is a rutinoid or a neohesperidoid is in progress.

Our thanks are due to Prof. S. Sankara Subramanian of the Jawaharlal Institute of Postgraduate Medical Education and Research, Pondicherry-6, for the supply of authentic dinatin used for comparison and to the University Grants Commission, New Delhi, and the Madurai University for the award of a Research Scholarship to one of us (S. M. K.).

### EFFECT OF MINERAL NUTRITION ON YIELD AND OIL QUALITY OF SUNFLOWER

EXPERIMENTAL data on the effects of mineral nutrition on the yield and oil content of sunflower, a recently introduced oil seed crop, are available in literature<sup>2-5</sup> but the role of mineral nutrient uptake on oil quality has not been studied. This aspect was investigated on a sandy loam soil at Agricultural College Farm, Bapatla, with two varieties of sunflower, viz., Sunrise and E.C. 68414.

The layout was a split-plot design, with the varieties being assigned to main plots and three dates of sowing combined with four levels of phosphate (0, 30, 60 and 90 kg  $P_2O_5$ /ha as superphosphate) being assigned to sub-plots: there were three replications. The crop received uniform dose of 60 kg N/ha as ammonium sulphate and 30 kg  $K_2O$ /ha as muriate of potash. In addition to the yield of seed, oil-yield was calculated from the per cent oil/in seeds estimated with Soxhlet's extraction apparatus (A.O.A.C., 1970). Attributes of oil quality were determined by standard procedures.

Data on the (maximum) uptake of major nutrients N, P and K at complete flower-opening as well as yield and oil quality attributes are given in Table I.

The variety Sunrise gave significantly higher yields of seed and oil as compared to E.C. 68414. For both the varieties the uptake of K was highest followed by N and P, though there were no differences in the uptake of each nutrient between the two varieties. Similarly, there were no marked variations in the acid value, saponification value and iodine value of oil for the two varieties.

The relation between the uptake of N, P and K at complete flower-opening and the yield as well as oil quality attributes are given in Table II.

Uptake of N, P and K at complete flower-opening were significantly correlated with both seed and oil yields, those with oil-yield being still higher. The acid value and iodine value bore significant correlation with uptake of N and K only but not with that of P. Nutrient uptake did not seem to influence saponification value of oil. Saponification value which is indicative of the presence of long chain fatty acid components seems to be a characteristic

TABLE II

Correlation of nutrient uptake at complete flower-opening with yield and quality of sunflower oil

| Correlation between | Yield of seeds | Yield of oil | Acid value | Saponification value | Iodine value |
|---------------------|----------------|--------------|------------|----------------------|--------------|
| Uptake of N         | 0.82**         | 0.89**       | 0.43*      | 0.19                 | 0.52**       |
| Uptake of P         | 0.62**         | 0.91**       | 0.32       | 0.35                 | 0.23         |
| Uptake of K         | 0.65**         | 0.85**       | 0.62**     | 0.15                 | 0.57**       |

\* Significant at 5%.

\*\* Significant at 1%.

of plant species, and is not so much influenced by nutrient uptake.

The present investigation revealed that sunflower variety Sunrise was superior to E.C. 68414 as regards the yield of seed and oil, though the uptake of N, P and K by the varieties did not differ much. The uptake of N, P and K at complete flower-opening was found to bear significant positive correlation with both seed and oil yield. The acid value and iodine value appeared to be affected by the uptake of N and K but not of P. Saponification value was not influenced by nutrient (N, P or K) uptake at complete flower-opening.

### ISOCITRATE DEHYDROGENASE IN RHIZOBIUM SPECIES

NICOTINAMIDE adenine dinucleotide phosphate may be a key electron carrier from which electrons are channelled to nitrogenase in *Azotobacter*<sup>1</sup>, nodule bacteroids<sup>2</sup> and blue green algae<sup>3</sup> from the general metabolic pool. A system generating NADPH could be coupled to bacteroid nitrogenase with bacteroid iron-sulphur proteins azotoflavin and ferredoxin NADP reductase<sup>4</sup>. The role of poly-beta-hydroxybutyrate dehydrogenase in rhizobia, which is linked to pyridine nucleotides, has been well studied<sup>5-6</sup>. The general dehydrogenase level

in various effective and ineffective strains has been reported<sup>7</sup>.

Isocitrate dehydrogenase (ICD) constitutes 1% of the total protein in *Azotobacter vinelandii* and its role in supplying NADPH (electrons) to nitrogenase has been suggested<sup>8</sup>. The enzyme has been reported in *Rhizobium* bacteroids<sup>2</sup>. However, cultured rhizobia produce glutamate dehydrogenase and aspartate and alanine aminotransferases but not isocitrate dehydrogenase, when given ammonia or amino acids<sup>9</sup>. Since very low ICD activity was detected in bacteroids, the supply of  $\alpha$ -ketoglutarate by the host plant during symbiosis has been suggested<sup>10</sup>. We report here the presence of ICD in all of the effective and ineffective species of rhizobia cultured *in vitro*.

*Rhizobium* strains were grown in a medium containing  $K_2HPO_4$  1.6 g,  $KH_2PO_4$  0.4 g, Yeast Extract 2 g,  $MgSO_4 \cdot 7H_2O$  0.2 g, NaCl 0.1 g,  $CaCl_2 \cdot 2H_2O$  0.09 g,  $(NH_4)_2SO_4$  0.5 g and Sucrose 20 g per litre in 500 ml Erlenmeyer flasks with 200 ml medium. A 10% inoculum was added and the flasks were incubated on a rotary shaker at 30°C. Cells were harvested during the late logarithmic phase and washed twice with 0.05 M phosphate buffer. Crude extracts were prepared by grinding the frozen cell paste with two parts of glass powder followed by extraction with 4 volumes of 0.005 M Tris-HCl buffer of pH 7.5. Unbroken cells and debris were removed by centrifugation at 4°C at 20,000  $\times$  g and the supernatant used for enzyme assays.

The enzyme was assayed spectrophotometrically by measuring the rate of reduction of NADP at 340 nm in presence of the substrate. The assay mixture contained DL-isocitrate (trisodium salt) 20  $\mu$ moles, NADP 0.5  $\mu$ moles,  $MnCl_2$  10  $\mu$ moles, Tris-HCl buffer pH 7.5, 40  $\mu$ moles. The reaction was started by addition of substrate<sup>11</sup>. Extinction was measured in a Beckman DU spectrophotometer.

Protein was estimated by the modified folin's method<sup>12</sup>. One unit is that amount of enzyme which catalyses the formation of 1  $\mu$ mole of reduced NADP per minute. Specific activity is expressed as units per mg protein.

Contrary to earlier reports, all strains of *Rhizobium* tested showed ICD activity (Table I).

TABLE I

| Strain                              | Description   | Specific activity of ICD (units/mg) |
|-------------------------------------|---|-------------------------------------|
| Obtained from C.S.I.R.O., Australia |   |                                     |
| <i>Rhizobium japonicum</i> CB 1809  | Effective for all varieties of <i>Glycine max</i> except Hardee and related lines | 0.18                                |
| <i>R. japonicum</i> CC 709          | Effective for <i>Glycine max</i>  | 0.07                                |
| <i>R. japonicum</i> CC 707          | Ineffective for <i>Glycine max</i>  | 0.061                               |
| <i>R. phaseoli</i> CC 502           | Effective for <i>Phaseolus vulgaris</i>   | 0.05                                |
| <i>R. phaseoli</i> CC 596           | Ineffective for <i>Phaseolus vulgaris</i>   | 0.051                               |
| Isolated in our laboratory          |   |                                     |
| <i>R. phaseoli</i>                  | Effective for <i>P. vulgaris</i>  | 0.13                                |

The level of the enzyme differs from species to species and there is no significant difference between the effective and ineffective strains. Differences in the cultural conditions used in the growth of *Rhizobium* could account for the inability of earlier workers to detect ICD.

We are indebted to Professor F. J. Bergerson, C.S.I.R.O., Australia, for the cultures of *Rhizobia*. The senior author thanks the C.S.I.R., New Delhi, for the award of a Junior Research Fellowship.

#### EPIZOOTIC SEPTICEMIA IN FROGS CAUSED BY *AEROMONAS HYDROPHILA*

AN investigation was carried out to determine the cause of the sudden death in the frog-tank of frogs in large numbers at this college (Fig. 1). The

FIG. 1. Photograph showing the dead frogs in the frog tank.

diseased frogs were very lethargic, and "punched" ulcers, over the knees, thighs, back and nostrils were seen. On application of pressure near the lesions, a straw coloured fluid exuded from the ulcers. The webs were bright red in colour. Few diseased frogs, tank-deposit, and the tank water were collected for bacteriological investigation. Scrapings from the ulcers, heartblood, deposit from

tank and water were inoculated in different media. *Aeromonas hydrophila* was isolated from all the above specimens to the exclusion of other pathogenic bacteria and fungi. All the isolates were oxidase positive and produced very clear halos of beta hemolysis on blood agar plates; they gave non-lactose fermenting colonies on MacConkey agar plates. The nature and characteristics were identical to that of *Aeromonas hydrophila* as described in the *Bergey's Manual of Determinative Bacteriology*<sup>3</sup>. Therefore it was identified as *Aeromonas hydrophila*.

*Aeromonas hydrophila* of the family Pseudomonadaceae is a common inhabitant of water as the very name suggests. It can also be isolated from soil, foods and rarely from the human intestinal tract<sup>2</sup>. It is pathogenic for frogs ("Red-leg" disease), salamanders, fish, mice, guinea pigs, rabbits and snakes causing hemorrhagic septicemia<sup>3,5</sup>, abortion in bovidae<sup>6</sup>, and 'black rot' in hen's eggs<sup>3</sup>. In our laboratory a tortoise also died of this infection but this animal was kept in a separate aquarium. There are a few reports of human infection caused by *Aeromonas hydrophila* like septicemia<sup>1</sup>, gastroenteritis<sup>2,4</sup>, cellulitis and cirrhosis<sup>2</sup>. One of the authors (K. N. A.) who handled these frogs with bare hands developed a 'Whitlow' in three to four days time presumably due to the same organisms. The pus smear showed gram negative bacilli.

According to the authors, so far, there is no report from India of the outbreak of "Red-leg" in frogs. This communication records an epidemic, the etiological agent clearly being *Aeromonas hydrophila*.

Thanks are due to the Dean and Professor of Physiology, K.M.C., Manipal, for the facilities provided.

## ON AN OCCURRENCE OF HIDDENITE FROM A PEGMATITE NEAR KABBUR, HASSAN DISTRICT, MYSORE STATE

THE paper describes the occurrence of a rare variety of spodumene, from a mica-pegmatite exposed at Kabbur. Rao and Rao<sup>1</sup> and Babu<sup>2</sup> have reported the occurrence of spodumene in India. The pegmatites occurring at Kabbur, are essentially mica bearing, belonging to Archaean age. The pegmatite is found traversing and sometimes associated with granitic gneisses. The pegmatite is generally coarse-grained, consisting of quartz, feldspar and mica. Both types of micas are seen in the pegmatite. Muscovite occurs in books of varying size, while biotite occurs sporadically interspersed in the pegmatite and occurs as streaks and irregular books. Garnet and black tourmaline occasionally are seen in the pegmatite.

The author collected a few crystals from the mines. The pegmatite, containing the spodumene crystals comprises highly crushed quartz and lustrous plates of feldspars. The pegmatite containing hiddenite is even textured and the microcline in the pegmatite is devoid of perthitic habit.

The mineral was crushed to pass through 80 mesh and the crushed material was subjected to heavy liquid separation. The material separated was almost pure but for the inclusions inside the mineral, which could not be separated. X-ray and optical data confirmed the identification of the mineral. The data on chemical analysis and X-ray are presented in Table I.

The crystal collected from the pegmatite dumps, was tabular, measuring 2" in length, with vertical furrows and striae. Very well developed one set of prismatic cleavage, exhibiting pearly lustre on the cleavage surface are seen. The colour ranges from emerald-green to apple green. On some portions of the crystal collected from the crushed pegmatite portion, alteration into a soft, yellowish-green to pale pink material is seen which may be cymatolite(?), as determined by the lithia content (0.20%).

*Chemical Study.*—The material separated in heavy liquid was chemically analysed. The major analysis was carried out after the method of Schapiro and Brannock<sup>3</sup> and the trace elements by the use of Atomic absorption spectrometer (Cu, Mg, Ca, Sr, Rb) and Spectrophotometer (Cr, Ti) and Emission Spectrograph (Be, B). The major and trace elemental analyses are presented along with the analysis reported in literature in Table I.

The chemical analysis compares well with the purplish-grey to greenish spodumene reported in Deer et al.<sup>4</sup> (p. 93). The mineral from Kabbur

|                                |        |        | Be             | 50       |
| Total                          | 100.13 | 100.60 | B              | 50       |

A—Hiddenite from Kabbur Pegmatite, Mysore. Analyst: S. K. Babu.

B—Purple-grey to greenish spodumene from Oorigum, K.G.F., Analyst: E. R. Thirumalachar.

has a slight excess of lithia in comparison to the one reported in literature.

The trace elements justifies the contention of Gabriel *et al.*<sup>5</sup>, "that the impurities exist as isomorphous replacements in the spodumene structure". Further, the presence of 1200 (ppm) of chromium probably explains the emerald-green colour of the hiddenite as well as its pale pleochroism.

The various studies carried out on the mineral points to the mineral to be a monoclinic pyroxene (spodumene) and further the emerald-green colour assigns to the hiddenite variety.

The author places on record his sincere thanks to Dr. R. Krishnan of the Metallurgy Division of the Bhabha Atomic Energy Research Centre for furnishing the X-ray data, and to the Heads of the

Divisions of Health Physics, Spectroscopy and Analytical Chemistry of BARC, for affording laboratory facilities to carry out the chemical and trace element analysis.

### RECORD OF A SPECIMEN OF MYSTUS MONTANUS (JERDON) WITH STUNTED PECTORAL SPINE

ASYMMETRICAL occurrence of paired organs in bilaterally symmetrical teleosts is rare. Instances of the loss of both pelvic fins such as in *Channa scopoli*, repression of the one pair of mandibular barbels as in *Silonia Swainson* (Majumdar<sup>1</sup>) are on record. However, dissimilarity in the growth of paired fins is not known. A specimen of *Mystus montanus* (Jerdon) 64 mm in length collected from the five falls forest, Courtallam, by the author, on 16-11-1973, has the right pectoral spine dissimilar in length, girth, nature of serration as compared to its counterpart on the left side. The specimen under report was collected from a rocky bottom, in a swift flowing stream of the river Courtallam at Courtallam, along with seven other normal samples of the same species, ranging in standard length from 45 to 85 mm. The spine does not appear to be of a secondary growth, nor injured. Compared to its counterpart on the left side, it is only 8 mm in length *versus* 12 mm of the left side with 4 antrorse teeth (*versus* 8). The serrations are feeble. Some data obtained on the two spines of the fish are as below :

|  |    |         |
|--|----|---------|
| Standard length of the fish                  | .. | 64 mm   |
| Head length                                  | .. | 16 mm   |
| Head length/left pectoral spine<br>(stunted) | .. | 1.06 mm |
| Head length/right pectoral spine             | .. | 1.14 mm |
| The number of pectoral fin rays :            |    |         |
| Right side                                   | .. | 1 + 8   |
| Left side                                    | .. | 1 + 6   |

The spine on the left side which is stunted is 4 mm shorter in length than its counterpart on the

right side, but the diameter is more or less same. The pectoral fin itself is normal.

# **BIFURCATED BARBEL IN A CATFISH *HETEROPNEUSTES FOSSILIS* (BLOCH)**

REPORTS on the abnormality of different organs in fishes have been made by many authors but literature on the presence of forked barbels in fishes are very few. Tandon and Sharma (1971)<sup>1</sup> and Ovais (1974)<sup>2</sup> have reported the presence of forked barbels in *Callichrous macropthalmus* and *Clarias batrachus* respectively. In the present communication a case of bifurcated barbel in *Heteropneustes fossilis* (Bloch) has been reported which appears to be the first report on the said species.

A female specimen of *H. fossilis*, exhibiting the abnormality, was collected from the local market at Barrackpore. The left innermost maxillary barbel of the specimen was observed to be bifurcated (Fig. 1). The length of the left branch of the

FIG. 1

abnormal barbel from the point of bifurcation was 1.7 cm and that of the right branch was 1.6 cm. The total length of the abnormal barbel was 2.8 cm up to the tip of its left branch and 2.7 cm up to the tip of its right branch. The unbranched corresponding normal right barbel was 2.8 cm. The total length/weight of the specimen was 15.8 cm/14.9 gm.

The cause of such abnormality could not be determined. Tandon and Sharma (1971)<sup>1</sup> were unable to produce forked barbed in experimental induced regeneration of barbels in *H. fossilis*. The abnormality in the fish described here may be due to mechanical injury of the barbel during its early development.

The authors are indebted to Dr. V. G. Jhingran, Director, for his encouragement and to Dr. P. V. Dehadrai, Project Co-ordinator, Air-breathing fish Culture and to Shri B. N. Saigal for helpful suggestions.

## SOME NEW MARKET DISEASES OF VEGETABLES

DURING recent years much attention has been paid to the post-harvest diseases of vegetables<sup>1-5</sup>. They not only inflict enormous losses to plant products during marketing and storage but also serve as sources of infection through seeds and other plant products. In the present paper, some of the new and interesting diseases of vegetables collected during a survey of the local vegetable markets are described. Symptoms of various diseases were recorded and the colours are recorded as per Ridgway's<sup>2</sup> color chart. The pathogen associated with the disease was isolated on Asthana and Hawker's medium 'A' and was identified. Pathogenicity of the organism was confirmed by inoculating the pathogens on healthy vegetables employing Granger and Horne's<sup>1</sup> method and the diseases have been described hostwise.

*Lagenaria vulgaris* (Dutch) Rusby. (Bottle gourd)

The infection started mostly from the blossom end of the fruit in the form of white patches which later on changed their colour to tawny olive. Some of the patches coalesced and the region beneath became soft. The deeper tissues of the fruit also showed the presence of the fungus. Later on, the entire fruit was affected and as a result, the inner portion of the fruit was completely destroyed. The fungus<sup>6</sup> responsible for the disease was found to be an isolate of *Aspergillus niger* Van Tiegh.

*Luffa cylindrica* Roem. (Sponge gourd)

A severe rot of this fruit was observed during the months of August and September 1973. The infection started either from the apical or basal end of the fruit as olive brown coloured necrotic areas. Some of the necrotic lesions coalesced and infected portion became pulpy. An isolate<sup>6</sup> of *Aspergillus niger* Van Tiegh. was found associated with the diseased fruits.

*Solanum melongena* L. (Brinjal)

The disease appeared in the form of verona brown coloured necrotic areas. These areas enlarged gradually and ultimately occupied major portion of the fruit. The rotted tissue produced a juice emitting foul odour. The disease was more common on deep purple variety than on green variety. Isolations<sup>6</sup> from the diseased portion yielded an isolate of *Aspergillus niger* Van Tiegh.

*Trichosanthes dioica* Roxb. (Parval)

The disease could start at any place on the fruit as ochraceous buff colour spots. The spots enlarged and their colour changed to tawny olive. Sometimes 2 or 3 spots coalesced and formed a bigger spot. On some of the older spots, black fruiting bodies were visible. Isolations<sup>3</sup> from the diseased portion yielded an isolate of *Phoma pomorum* Thum.

*Zingiber officinalis* Rose (Ginger)

The disease started as ochraceous buff to tawny olive coloured irregular depressed areas on the surface of rhizome. These areas, later on, increased in size and occupied major portion of the rhizome. The internal tissue of the rhizome developed a dry rot. In the case of severe infection, the rhizome became smaller in size and lighter in weight. An isolate of *Rhizopus oryzae* Went. and Prinsen was found responsible for the disease. The morphological characters of the isolate were similar to those described by Yamamoto<sup>7</sup>.

Authors are grateful to Prof. D. D. Pant for providing laboratory facilities and to Dr. A. Johnston, Director, C.M.I., Kew, for his help in confirming the identity of pathogens.

## A RAPID METHOD FOR DETERMINATION OF OSMOTIC POTENTIAL OF PLANT CELL-SAP

IN the study of plant-water relationships assessment of water potential and osmotic potential are important, particularly in plants grown under saline stress, where osmotic potential determines the plant growth<sup>1-4,7</sup>. There are two major methods to determine osmotic potential (osmotic pressure,  $\pi$ ) of plant cell-sap: (a) freezing point depression and vapour pressure method and (b) plasmolysis<sup>1-3</sup>. Both these methods are accurate but rather difficult and time-consuming.

The United States Salinity Laboratory observed that the OP (atm.) of the soil solution is approximately equal to 36% of the electrical conductivity measured in millimhos/cm<sup>6</sup>. Furthermore, the conductivity of soil or plant extract gives a measure of the quantity of salt present. As such it is apparent that moisture content of plant tissue should also be considered. At a given temperature, the OP of a dilute solution is directly proportional to its solute concentration<sup>5</sup>. The OP of non-electro-

lytes is normally very much lower than that of electrolytes. Hence, in the present investigations the use of conductance measurements for the determination of OP has been extended to plant samples. The relation  $OP = 0.36 \times EC \times 10^3 \times$  dilution factor is used in the case of *Rhoeo discolor* leaves, and compared with the standard plasmolytic method. The details are as follows:

One g of fresh leaves of *Rhoeo discolor*, Hance, was ground to a paste in a porcelain mortar, strained through a muslin cloth and made upto 25 ml with distilled water. The electrical conductance of the expressed cell-sap was measured in a 'Elico' conductivity bridge. Moisture content of *Rhoeo* leaves was measured following standard methods of plant analysis. The OP in bars of *Rhoeo* cell-sap was then calculated as:  $=(EC \times 0.36 \times \text{d.f.})/0.987$ , where, EC = electrical conductance in millimhos/cm at 25°C of plant extract; d.f. = dilution factor depending upon the moisture content of the tissue and extract volume:  $0.987 =$  factor for converting atmospheric pressure to bars.

For comparative purposes, OP of *Rhoeo* cell-sap was also determined by standard plasmolytic method, using sucrose as a plasmolytic agent<sup>1,2</sup>. Ten samples were analysed by each method. The results are presented in Table I.

TABLE I  
Osmotic potential of *Rhoeo* cell-sap in bars\*

|   | New method | Plasmolytic method | 'r'    |
|---|------------|--------------------|--------|
| After accounting for moisture in tissue | -7.05      | -7.32              | 0.91** |

\* Mean of ten samples.  
r = Correlation coefficient.  
\*\* Significant at 0.01 P.

TABLE II  
Osmotic potential of sunflower leaves†

| Salinity gm salt/kg of soil (NaCl+CaCl <sub>2</sub> 4:1) | OP in bars | % decrease over control |
|--|------------|-------------------------|
| 0  | -6.13      | ..                      |
| 1.5  | -6.44      | 5.2                     |
| 3.0  | -8.74      | 42.6                    |
| 4.5  | -10.61     | 73.1                    |

† Average of duplicate samples.

The OP, obtained after accounting for moisture (94.3%) in the tissue by the new method, was slightly lower than that obtained by plasmolytic method (Table I). However, there was a highly significant correlation between the two methods.

Applying the new method, the OP was determined using the leaves of a twenty day old sunflower seedlings (*Helianthus annuus* L. var. Sunrise) grown under three salinity levels. The data in Table II indicate decreased OP of plant cell-sap with increase in salinity level. These findings are in conformity with the views expressed by Kramer<sup>4</sup> and Slatyer<sup>7</sup>.

The proposed new method will be of immense use when large samples are to be investigated for the OP of the plant cell-sap.

The work was supported from the grants by I.C.A.R. Thanks are also due to Dr. K. S. Krishna Shastry, Professor of Crop Physiology, for his helpful suggestions.

#### IN VIVO PRODUCTION OF TRANSELMINASE BY *HELMINTHOSPORIUM APATTARNAE* (DESH. & DESH.)

SINCE Albersheim *et al.*<sup>1</sup> and Nagel and Vaughn<sup>2</sup> reported the non-hydrolytic split of 1,4-glucosidic bonds in pectic substances, many workers tried to explain the role of transeiminative enzymes in the disease development by demonstrating their *in vitro* production by various plant pathogens. But little is known about *in vivo* production of these enzymes. Therefore, an attempt has been made to detect the transeiminase (TE) in the rotted potato tuber caused by *H. apattarnae*.

Fresh and healthy potato tubers were brought from market. They were surface sterilized with rectified spirit in the inoculation room already sterilized with ultra-violet light. After sterilization, 2" deep cavities were made into each tuber with the help of sterile cork-borer diameter 8.0 mm. Five drops of spore suspension prepared from six day old slope culture of *H. apattarnae* were placed in each cavity and potato cylinders were replaced. Potato tubers were inoculated similarly with sterile distilled water and used as control. Tubers were incubated for 7 days at  $25 \pm 1^\circ \text{C}$ . All tubers were placed in the sterilized tin box to avoid contamination. After incubation period, tubers were cut transversely to scrap the rotten portion and its weight was recorded. It was later crushed in mortar with pestle by adding distilled water in 500:1 (mg/ml). The extract was filtered with fine cloth and then centrifuged at 5,000 rpm for 10 minutes to make it cell free. The pH of the supernatant fluid was noted by a pH meter and it was then used as enzyme solution and enzyme activity was determined spectrophotometrically at pH 6.7 and 9.7 by using the procedure of Ayers *et al.*<sup>3</sup>.

TABLE I

*In vivo* detection of transeliminase activity at pH 6.7 and 9.7

| Wave-length (m $\mu$ ) | Absorbance |        |                |        |

| 230                    | 0.0996     | 0.1107 | 0.073          | 0.0809 |
| 232                    | 0.1308     | 0.1427 | 0.0756         | 0.073  |
| 234                    | 0.127      | 0.1612 | 0.073          | 0.0757 |
| 236                    | 0.1107     | 0.1135 | 0.073          | 0.0706 |
| 238                    | 0.1051     | 0.0969 | 0.0706         | 0.0706 |
| 240                    | 0.015      | 0.0942 | 0.068          | 0.063  |

Activity of TE was absent in the extract of healthy potato tuber. Extract of potato tuber infected by *H. apattarnae* had shown activity. The TE activity was maximum at pH 9.7 in both the substrates. It was more at pH 9.7 in pectin than in sodium-polypectate solution. Absorption was maximum at 234 m $\mu$  in pectin and at 224 m $\mu$  wavelengths in sodium-polypectate respectively.

*In vivo* detection of these enzymes have been reported by various workers in the case of different fungi. But as regards the activity of these enzymes, different results are obtained for *Fusarium oxysporum* and *F. solani*, Papavizas and Ayers<sup>3</sup>, and *Alternaria compacta* Punde<sup>6</sup>. On the other hand, Heath and Wood<sup>2</sup> could not get polygalacturonate transeliminase activity in the extracts of *Myrothecium pinodes* affected lesions. Studies on *in vivo* production of transeliminases by *H. apattarnae* clearly indicated that the fungus secretes enzymes which are capable of degrading pectic substances transeliminatively. It can be concluded that transeliminases also appear to play an important role in disease development.

#### EFFECT OF GAMMA IRRADIATION OF SEEDS ON SOME MORPHOLOGICAL CHARACTERS AND SEX EXPRESSION IN MUSKMELON (*CUCUMIS MELO* L.)

SEX expression may be affected by a number of agencies such as light, temperature, mineral nutrition and growth regulators in plants<sup>1</sup>. There are a few reports regarding the effect of gamma irradiation on sex expression in plants<sup>2,3</sup>. The present investigations were undertaken to elucidate the effect of gamma irradiation of seeds on length of vine, nodes, lateral branches, sex expression and pollen sterility in *C. melo* L.

The investigations were carried out from the middle of February to middle of June, 1973. Healthy seeds were dried in the sun for five days (10 a.m. to 4 p.m., 26–30° C). The seeds were

\* Significant at 5% level.

† Not significant.

irradiated with five doses, viz., 0.5, 1.0, 1.5, 2.0 and 2.5 kR from Co<sup>60</sup> source of gamma rays at a dose rate of 2100 R/minute in air. Two hundred seeds were irradiated for each dose. Seeds of *C. melo* cv Hara Madhu were sown on the one side of 30 m long and 8 m wide plots. Three replicates of ten plants were taken for each dose. Pollen sterility % was isolated by germinating pollen in 10% sucrose and 3% agar medium.

Irradiation of seeds increased the length of vines, the number of nodes and lateral branches upto 1 kR and with higher doses these factors decreased (Table I). The first staminate flower appeared on higher nodes while the first hermaphrodite flower appeared on lower nodes up to 1 kR. Irradiation with higher doses did not affect the position of first hermaphrodite flower but increased the node number to the first staminate flower. Irradiation upto 1.5 kR increased the number of hermaphrodite flowers, 2.0 kR had no significant effect and 2.5 kR reduced it drastically. Number of staminate flowers decreased progressively with increase in dose. Irradiation caused a shift towards hermaphrodite flowers. Pollen sterility increased gradually with increase in dose (Table I).

Our findings suggest that 1.0 kR irradiation is an effective dose for inducing better vegetative growth. Similar results have also been reported for *Cucumis sativus*<sup>2</sup> and *Lycopersicum esculentum*<sup>5</sup>. The irradiation of seeds suppresses maleness and promotes femaleness. This clearly shows that irradiation has properties opposite to gibberellins. Gibberellins are known to induce maleness<sup>4,7</sup>. Recently it was found that irradiation induced ethylene production<sup>6</sup>. It is, therefore, possible that irradiation exerts its effect on sex expression through ethylene evolution system. Ethylene has also been reported to cause femaleness<sup>7</sup>.

Financial assistance from the Department of Atomic Energy, Government of India, to A. K. Bisaria is appreciated. Thanks are extended to the authorities of INMAS for gamma irradiation facility.

### COLCHICINE INDUCED AMPHIDIPLOID BETWEEN MUNG (*PHASEOLUS AUREUS* ROXB.) AND URD (*PHASEOLUS MUNGO* L.)

INTERSPECIFIC hybridization is resorted to when the desired character is not found within the species. But in most of the cases, the fertility of species hybrids has been found to be very poor. The fertility of such hybrids may be restored through chromosomal doubling. Colchicine treatment is one of the efficient techniques of doubling the chromosomes. Sen and Ghosh<sup>1</sup> and Dana<sup>2</sup> attempted the cross between mung (*Phaseolus aureus* Roxb.) and urd (*Phaseolus mungo* L.) and reported that the fertility of  $F_1$  was very low. The present investigation was undertaken to overcome the problem of fertility in the aforesaid species hybrid by the colchicine treatment.

parent. Three  $F_1$  seedlings were treated each with 0.25, 0.50, 1.00 and 1.50% aqueous solution of colchicine at two leaf stage during *kharif* 1972. The reagent was applied at the shoot apex for half an hour daily for seven days. Observations were recorded and polyploid plants were identified. During *kharif* 1973 amphidiploid  $F_1$  and the parents were grown in a completely randomised design with 5 replications.

#### Results and Discussion

Three seedlings were treated each with 0.25, 0.50, 1.00 and 1.50% aqueous solution of colchicine. One colchipsoid plant was obtained with 0.25% and three plants with 0.50% concentration. Polyploidy could not be induced with 1.00 and 1.50% colchicine.

The colchicine treatment resulted in the inhibition of seedling growth. The seedlings showed abnormalities like swelling of stem apex, thickening of stem and leaves and broadening of leaflet and flower size, etc. The seedlings which were treated with 1.00 and 1.50% colchicine died after some time.

The amphidiploid differed significantly from the  $F_1$  in respect of length and width of leaflet, stipule and flower (standard); number of cluster/plant; number of pod per cluster; pod length; number of seed per pod and 1000 grain weight (Table I).

TABLE I

Comparison of characters of amphidiploid,  $F_1$  and parents (mung T.44 and urd T.9)

#### UTILIZATION OF SULPHUR COMPOUNDS BY *ALTERNARIA TRITICINA*

PRASADA AND PRABHU<sup>2</sup> reported a leaf blight disease of wheat and identified the pathogen as *Alternaria triticina* Prasada and Prabhu. The disease has assumed epidemic proportions in India, with the introduction of high yielding varieties having 'durum' blood. A detailed investigation of nutritional requirements and host pathogen relationships of this pathogen has been taken up in this laboratory and the effect of different sulphur compounds on the growth of *Alternaria triticina* is presented here.

Czapek-Dox liquid medium with 3% sucrose was used as the basal medium. Different sulphur compounds were added to the medium in quantities which supplied the same amount of sulphur present in 0.5 g of  $MgSO_4 \cdot 7H_2O$ . The pH of the medium was adjusted to 5.0 before sterilization. The flasks containing 25 ml of the medium were seeded with 1 ml aliquots of uniform spore suspension. The cultures were incubated at room temperature (25–30° C) in dark and the growth of the fungus was determined as dry weight of mycelium after 10 days. For each treatment four replicates were maintained. The pH values of the culture filtrates were also recorded.

From the data (Table I) it is evident that *A. triticina* shows significant differences in the utilization of different sources of sulphur. Magnesium sulphate supported maximum growth. The same effect was reported by Hasija<sup>1</sup> for *A. citri* and *tenuis* and by Singh and Khanna<sup>4</sup> for *A. tenuis*. The latter fungus is frequently associated with blighted wheat leaves as a saprophyte<sup>3</sup>. Sodium sulphate, sodium thio-sulphate, sodium bisulphate, potassium bisulphate, sodium sulphite, potassium thiocyanate, ammonium sulphate and potassium persulphate supported progressively less growth of the fungus. There was no growth on potassium metabisulphite and growth was very poor on thiourea which may be, as

TABLE I  
Effect of different sulphur compounds on the  
growth of *Alternaria triticina*

| Sulphur source           | Dry wt. of<br>mycelium<br>in mg<br>(Average of<br>4 replicates) | pH values of<br>culture<br>filtrates |
|--------------------------|---|--------------------------------------|
| Ammonium sulphate        | 107   | 6.3                                  |

reported by Lily and Barnett<sup>2</sup>, due to the inability of the pathogen to break the carbon sulphur bond. Generally there is an increase in the pH values of the culture filtrates (5.5–8.0) where there was growth. The results indicate that *A. triticina* is capable of utilizing a wide variety of sulphur compounds but the growth response is better on sulphates.

## EFFECT OF ETHREL ON ASCORBIC ACID OF COFFEE FRUITS

ETHREL spray on plants releases ethylene directly to plant tissues producing numerous physiological effects and regulate plant development, out of which hastening of fruit ripening is one<sup>1</sup>. As in other fruits, in coffee also the natural ripening agent is ethylene<sup>2</sup>. After spraying ethrel on mature green coffee fruits, it enters into fruit cells, releases ethylene and hastens the ripening process<sup>3</sup>. Since quantitative changes of ascorbic acid are depended mainly on carbohydrate metabolism<sup>4</sup>, changes in its content may occur with ethrel spray which was found to influence the carbohydrate metabolism in ripe coffee fruits (Authors' unpublished work).

During 1973 crop season, nine plants of *Coffea arabica* L. cv. S. 795 at random were sprayed each with 750 ml aqueous solution containing 0.5 ml ethrel (2-chloroethane phosphonic acid, an Amchem product, Ambler, U.S.A.). The plants (19 years old) were grown under natural shade at Central Coffee Research Institute. The fruits were sprayed when they were in mature green condition. Thirteen days after spray, fully ripe fruits were collected from sprayed plants and also from nine control (unsprayed) plants at random from the same plot. Fruit wall, mucilage and seed were separated and their ascorbic acid was determined<sup>5</sup>.

The ascorbic acid was significantly (at 1%) lower in fruit wall with ethrel spray as compared to that of control, whereas in mucilage it was significantly (at 1%) more with ethrel treatment than of control (Table I). Even though the vitamin content was more in seeds by about 9% with ethrel spray as compared to control, the increase was not statistically significant.

TABLE I

Effect of ethrel spray on ascorbic acid (mg/100 g fresh weight) in ripe fruits of *arabica* coffee cv. S. 795

| Fruit component | Control (unsprayed) | Ethrel sprayed | C.D. at |      |

| Seed            | 45.15               | 49.02          | NS      | NS   |
| Total           | 51.75               | 51.85          |         |      |

NS: Not significant.

Distribution of ascorbic acid in different components of green and ripe fruits of five coffee types belonging to three coffee species, and of pulp and

pulped water of bulk arabica has been reported<sup>6-8</sup>. However, ethrel spray has not caused any adverse effect on ascorbic acid content in the fruits as a whole, except for the quantitative changes in different fruit components as compared to the fruits of control (unsprayed) plants.

The authors are grateful to Dr. G. I. D'Souza, Director of Research, for encouragement. They also thank Messrs. Agromore Limited, Bangalore, for the free experimental sample of ethrel.

## TWO NEW DISEASES OF SAFFLOWER FROM INDIA

SAFFLOWER (*Carthamus tinctorius* Linn.) is an important oil seed crop cultivated in several States of India. During survey in Varanasi and Mirzapur Districts, two new root diseases were observed.

### 1. Wilt of Safflower

The disease appears at different growth stages. A characteristic symptom is unilateral yellowing of the foliage followed by wilting (Fig. 1). Half of the leaf gets discoloured with the midrib usually curved towards the chlorotic side. Some plants look stunted coupled with dark green foliage and with distorted shape. Yellowing starts from the lower leaves and progresses upward. The affected leaf tissue generally turns brown and gets killed. Dark brown discolouration in the vascular tissues can be traced from the root to the upper part of the stem (Fig. 2). In a few cases creamy white mycelium was observed at collar region progressing externally upward on the stem.

The pathogen was isolated on P.D.A. from diseased roots. Mycelium delicate, white or peach usually with a purple tinge, sparse to abundant then floccose becoming felted and sometimes wrinkled in old cultures. Microconidia borne on simple phialids arising laterally on the hypha or on short sparsely branched conidiophores, abundant, oval-ellipsoid cylindrical, straight to curved,  $5-12 \times 2.2-3.5 \mu$ . Macroconidia sparse borne on more elaborately branched conidiophores. They are thin walled, generally 3-5 septate, fusoid-subulate and pointed at both ends. Three septate spores in range  $27-46 \times 3-4.5 \mu$  is most common. Chlamydospores smooth walled, generally abundant and are both terminal and intercalary, usually solitary but occasionally formed in pairs.

The fungus has been identified as *Fusarium oxysporum* f. sp., *carthami* and has been confirmed by C.M.I. (IMI-166917). Pathogenicity test was proved following the method suggested by Klisiewicz and Thomas (1970).

The disease was first reported from California (Klisiewicz and Houston, 1962) and this is the first report of its occurrence in India. The disease incidence was estimated at 5-15% in most of the fields but in some it was as high as 25%.

## 2. Damping-off of Safflower

The disease was observed at a very early stage. In the morning hours affected plants droop and topple over either individually or in patches. The emerging radicle gets infection and soft lesion formed which progresses upward causing death of the seedling (Fig. 3). The fungus was isolated from diseased seedlings on P.D.A. Cultures at first white with floccose aerial mycelium tinged with peach but after 7-14 days changed to beige and finally to deep olive buff. From below initially peach coloured changing to vinaceous fawn and finally dark brown. Conidia at first sparse and produced on simple lateral phialids,  $10-12.5 \times 2.5-3 \mu$ , on aerial mycelium. After about 14 days conidia are more abundant with the production of compact penicillately branched conidiophores. These arise from a lateral branch which initially may be of one cell and bears 2-4 phialids at the apex, or 2-4 branches may form at the apex, each of which may produce several phialids. These phialids are generally obclavate,  $12-17 \times 3-4 \mu$ . Sporodochia generally absent. The conidia are falcate with a well developed pedicellate foot cell and an attenuated apical cell which is bent inwards exaggerating the normal curve of the spore. Mature conidia have 4-7 thin but distinct septa measuring  $22-60 \times 3.5-5.9 \mu$ . Chlamydospores intercalary, solitary, in chains or in knots, globose,  $7-9 \mu$  in diameter. Intercalary

chlamydospores in the mycelium are formed singly or in chains. Perithecia not observed.

FIGS. 1-3. Fig. 1. Wilt of safflower incited by *Fusarium oxysporum* f. sp. *carthami* showing unilateral wilting. Fig. 2. Vascular discoloration of safflower roots due to *F. oxysporum* f. sp. *carthami*. Fig. 3. Damping off of safflower seedlings incited by *F. equiseti*.

The fungus has been identified as *Fusarium equiseti* (Corda) Sacc. and confirmed by C.M.I. (IMI-166921). Pathogenicity test was proved following method suggested by Klisiewicz and Thomas (1970). Damping-off of safflower incited by *F. equiseti* is a new disease reported for the first time.

Cross inoculation tests on young seedlings and 21 day old plants of safflower were carried out and invariably negative results were obtained. Thus confirming that the above two diseases are distinct and are incited by two different organisms.

Thanks are due to Dr. C. Booth of the Commonwealth Mycological Institute, Kew (U.K.), for confirming the identification. Thanks are also due

to CSIR, New Delhi and UGC for award of fellowships to AKS and DKC respectively.

# REVERSAL OF CHLORAMPHENICOL INHIBITED GROWTH BY RIBOFLAVIN IN GREEN GRAM (*PHASEOLUS RADIATUS* L.)

UNTIL recently it was felt by many physiologists that no B vitamin is implicated in protein synthesis. The concept that B vitamins act merely as catalysts and coenzymes is becoming more and more fluid. By virtue of possessing a pyridine ring as the principal chemical constituent with nitrogen as an essential element. B group vitamins appear to influence many physiological processes. The present knowledge as to what physiological processes are influenced by B vitamins is very cursory. That nicotinic acid effects nucleic acid and protein synthesis as well as growth and yield was shown by Bogdonova<sup>1</sup>. The present study was designed to understand the mechanism of action of riboflavin (B<sub>2</sub>) in chloramphenicol inhibited growth. Considerable literature is available concerning the protein inhibiting nature of chloramphenicol.

Green gram seeds (cultivar) were subjected to presowing treatment for 24 hr in 20 ppm of chloramphenicol, 20 ppm of riboflavin and their combination in Petri dishes in a luminosity of 1000 Lux and at 25° C ± 1° after which the seed-

lings were transferred to distilled water and allowed to grow for a period of one week. The starch content was estimated according to the method of McCready *et al.*<sup>2</sup>. The activity of amylase was determined by the method of Bernfeld<sup>3</sup>. The growth of the seedlings was measured in terms of fresh and dry weights as well as length of the seedlings.

The fact that chloramphenicol is an inhibitor of protein synthesis was well established<sup>4</sup>. Prior to its action on protein synthesis it appears from the present study that the hydrolysis of starch to reducing sugars is inhibited thus reducing the substrate for respiration consequently affecting growth. The action of chloramphenicol on starch hydrolysis (as evinced by amylase activity) may be preceded by its action on protein synthesis as starch is the first metabolite to be acted upon. This statement can be substantiated by the observation made by Nurten<sup>5</sup> that the primary action of chloramphenicol is in the inhibition of water uptake and water permeability in potato.

Riboflavin treatment caused an increase in starch hydrolysis which is also associated with increase in growth. An earlier report by Gopala Rao<sup>6</sup> indicated that riboflavin increases respiration, protein and chlorophyll content. In the present study it was observed that although starch hydrolysis is high the activity of amylase is low which may be apparently due to an inhibitory action of riboflavin on the enzyme amylase. It is quite possible that other enzymes concerned with starch hydrolysis, *viz.*, starch phosphorylase are activated. It is a well-known fact that enzymes such as R, and Z, P and Q are also involved in starch hydrolysis<sup>7</sup>.

The reversal of chloramphenicol inhibited growth by riboflavin (78% on the fifth day—Table I) supports the earlier observation by Gopala Rao<sup>6</sup>

that riboflavin activates protein synthesis thus causing an increase in growth of the seedlings (50% over control on the 4th day in the present study). With reference to the interaction of riboflavin and chloramphenicol on amylase activity the values are intermediate between riboflavin and chloramphenicol indicating the capacity of riboflavin to partly nullify the effect of chloramphenicol even with regard to amylase activity.

The authors thank Prof. V. S. Rama Das for providing facilities and his constant encouragement.

#### CHROMOSOME NUMBER OF THE PARAMPHISTOME [*GIGANTOCOTYLE EXPLANATUM* (NASMARK, 1937)]

THE Paramphistome group of digenetic trematodes are important from medical as well as veterinary standpoints in view of their common infestation of animals and humans. Divergences of opinion and ambiguities exist regarding their cytology and

- Bogdonova, E. D., *Sov. Plant Physiol.*, 1965, 12, 125.

taxonomy. Reliable descriptions of chromosome numbers, their behaviour and karyotypes of several Paramphistomes have not been available<sup>1-10</sup>. There is also a lack of knowledge on the chromosomes of several unexplored species from these angles. *Gigantocotyle explanatum*<sup>11,12</sup> is one such parasite commonly found in the livers, bile ducts and the gall bladders of domesticated ruminants. The chromosome number of this Paramphistome has been reported here.

The adult parasites were collected from the livers of buffaloes. Out of twenty livers examined fourteen of them showed heavy infection. They were processed for the chromosome analysis by the method described earlier by the authors<sup>13,14</sup>. All the divisional stages were traced to the haematoxylin squashes of testis of forty parasites.

The chromosome number was established as  $2n = 18$  from the counts of fifty well spread spermatogonial metaphases. A representative karyotype is presented in Fig. 1. It consists of five pairs of submetacentric, two pairs of metacentric (pairs 6 and 7) and two pairs of acrocentric (pairs 2 and 9) chromosomes. The number was also confirmed by screening two hundred meiotic stages. The chromosomes seen during diplotene (Fig. 2), very late diakinesis (Fig. 3) and metaphase I (Fig. 4) corroborate the above observation. Basing observations on gametogenesis of *G. bathycotyle* from sectioned material, Willmott<sup>1</sup> described the number as  $2n = 12$  consisting of eight short and four long chromosomes. It was also further opined

that no accurate counts and descriptions were possible. Much of reliance cannot, however, be placed on sections for such critical observations in view of their limitations. The chromosome number of the only other species of the same genus unexplored from this aspect has been established here as  $2n = 18$  along with the classification. This indicates that there is a variation in number at the level of the species. While Short and Menzel<sup>15</sup> contended that only the genera could be distinguished based on chromosome numbers, the results reported here are relevant in that such a distinction could be made not only within a genus but between species.

The authors are thankful to Profs. O. S. Reddi and P. Ramachander Rao for their interest and to Dr. T. Vasudev for the identification of the parasite.

**EXPERIMENTAL INDUCTION OF  
"INTERCOTYLEDONARY INTERNODE" IN  
MATURE EMBRYOS OF *AZADIRACHTA INDICA*  
A. JUSS.**

RECENTLY it has been shown that the excised embryos of *Azadirachta indica* grown in distilled water or simple mineral solutions exhibit rare morphogenetic responses<sup>1</sup>. The phenomenon included the production of callus followed by bud formation in the plumular region in entire and decapitated seedlings. While conducting surgical experiments on the mature embryos of *A. indica* the present authors noticed another rare morphogenetic expression—the production of an "intercotyledonary internode" between the two cotyledons.

The mature embryos exhibit two cotyledons disposed in an opposite manner. During the present study a majority of the germinating seedlings maintained this condition. However, the embryos subjected to surgical treatment behaved differently.

The embryos were removed from mature fruits which were opened after surface sterilization with 70% alcohol. After soaking them in sterile distilled water for an hour the brown seed coat was removed exposing the cotyledons and the embryonal axis. The hypocotyl apex was removed by a transverse cut with a sterile blade. After this operation the embryo was allowed to grow in sterile petri dishes over cotton wads soaked in Hoagland's mineral solution. While a majority of the treated embryos developed a hypocotyl and adventitious roots and retained the cotyledons in an opposite position, a few were different. The latter showed the displacement of the cotyledons from the opposite position to an alternate one. In this process an internode was formed between the two cotyledons (Fig. 1).

FIG. 1. *Azadirachta indica*. Photograph showing a seedling with intercotyledonary internode (Arrow). Vertical bar is 5 mm. C, Cotyledon; E, Epicotyl; H, Hypocotyl.

It was thought that a re-examination of the alignment of the cotyledons in a large number of embryos may reveal the prevalence of alternate condition in some. A survey indicated that the cotyledons were so closely situated on the embryonal axis that it was difficult to discover incipient 'internodes' between cotyledons. The surgical removal of the hypocotyl apex was repeated and the embryos grown on mineral solutions. It was later discovered that the occurrence of intercotyledonary internodes was frequent in specimens which accidentally received a superficial

FIG. 2. *Azadirachta indica*. Diagrams showing the disposition of vascular tissues in the seedling shown in Fig. 1. A, Transverse section through the upper cotyledonary node. B, Transverse section through the intercotyledonary internode. C, Transverse section through the lower cotyledonary node. surgical injury just below one of the cotyledons. An anatomical study of such embryos (Fig. 2, A-C) indicated that the injury was confined to a side of the axis and did not reach the vascular cylinder. There was initiation of cork cambial activity in the injured region. The elongation of axis lying between the cotyledons resulted in the formation of the 'intercotyledonary internode' and consequent change from opposite to alternate condition of the cotyledons. It was found that the intercotyledonary internode elongated like any normal internode and the distance by which the cotyledons were separated was considerable, being up to 10 mm in 15 days.

The altered nodal condition was studied in transverse sections of the axis (Fig. 2, A-C). It was found that a central double strand and two laterals were given off to each cotyledon. Cambial formation in the intercotyledonary internode was normal. Secondary phloem and xylem were formed. There was normal disposition and differentiation of phloem fibres.

The formation of the intercotyledonary internode indicates that alternate 'phyllotaxy' of the cotyledons may be a possibility. This is likely to alter the emphasis on theories which are based on the opposite condition as a general rule. It is likely that surgical injury in this experimental study induced the incipient internodes to develop fully and result in alternate cotyledons.

### PLEUROTUS SAJOR-CAJU (FR.) SINGER, A PROTEIN RICH NITROGEN FIXING MUSHROOM FUNGUS

In a search for new sources of protein food to improve the nutritional quality of our diet we came across an edible mushroom in *Pleurotus sajor-caju* (Fr.) Singer which has been reported to produce sporophores in the greenhouse under artificial culture<sup>1</sup>. The fungus has been found to grow readily on farm wastes, producing sporophores and in the process fixing atmospheric nitrogen to enrich the substratum.

The data in support of this are presented in this paper.

Pure cultures of *Pleurotus sajor-caju* obtained from Dr. C. L. Jandaik, Indian Agricultural Research Institute, New Delhi, was used in these studies. Fresh isolates of the fungus were obtained from fresh sporophores, by the tissue culture method and were maintained on oatmeal agar slants. For *in vitro* study the fungus was grown on synthetic media<sup>2</sup>, without nitrogen source. Analar grade chemicals and double distilled water were used to avoid nitrogen in the medium. For spawning beds maize grain spawn<sup>3</sup> was used. A mixture of paddy straw, wheat straw and hulled maize cobs in the ratio of 1 : 1 : 1 (W/W) was used as a substrate (bed) for the production of the mushroom. The substrate was pre-soaked for 12 hr in water and spread in trays (60 × 45 × 15 cm) and spawned with about 500 g of grain spawn. Estimation of protein<sup>4</sup> in the sporophores and the spawned substrate was carried out at periodical intervals.

The growth *in vitro* and protein content of *P. sajor-caju* estimated at periodical intervals are presented in Table I. The fungus not only put forth

|------------------------------|---|----------|
| Total N in the beginning     | : | 7.44 g   |
| N fixed through sporophore   | : | 63.36 g  |
| N fixed in the substratum    | : | 46.08 g  |
| Total N fixed during 60 days | : | 109.44 g |

after which there is a decline. The increased protein content of the substratum indicates positively the N-fixing capacity of the fungus. Sporophores appeared from 20–25 days after inoculation of the bed and contained 34.5% protein, on dry weight basis. After the harvest of sporophores, the substrate contained protein, varying from 15 to 18%. The sporophores are tasty and delicious as a protein-rich food and the substrate with enriched nitrogen could be used as manure to crop fields. *P. sajor-caju* has also been successfully raised on the stem bits of bhendi, brinjal and papaya, mixed in equal proportions with paddy straw and wheat straw.

## SHORT SCIENTIFIC NOTES

### Bacterial Cultures as Possible Analogues of Chemical Fertilizers

Since the pioneering work of Winogradsky<sup>1</sup>, the use of bacterial culture to ameliorate soil fertility has attracted much attention of the microbiologists. In the wake of power crisis, shortage of petroleum products, and spiralling rise in price of chemical fertilizers, researches are continuing in laboratory and field. Field measurements of  $N_2$  fixation in Californian soils have revealed dramatic rise in the activity when soils are inoculated with azotobacters or clostidia *plus* carbohydrate<sup>2</sup>.

Along with a basal amendment of phosphate, several sources of azotobacter cultures (JNKVV<sup>a</sup>, Bactogin<sup>a</sup>, Biofertilizers<sup>b</sup> and Bafe<sup>c</sup>) were applied to wheat, Narmada-4 under dryland conditions during 1973-74. The germinability and grain yield of single row treatment were noted. The Bafe brand culture could increase the germinability by 50%, and the yield by 11% in a non-significant manner (control = 738 g/5 m row). The observed increment in germinability and in yield were within the limits of field experimentation, and tallies with the report of Mishustin<sup>3</sup>.

Research data revealed that the inclusion of dimers of aldose-alonic acid mixtures is necessary for making the bacterization agronomically sound. Another trial with this type of culture prepared as described<sup>1</sup> was laid out with adequate statistical controls using combination of half and full recommended doses of nitrogenous fertilizer (15 and 30 kg N ha<sup>-1</sup>) with basal application of 30 kg P<sub>2</sub>O<sub>5</sub>/ha. Azotobacter culture was applied to the seed at the rate of 5 g/kg. Bacterization was found to be equivalent to 15 kg N ha<sup>-1</sup>, increasing the yield by 43% (control yield = 12.5 q ha<sup>-1</sup>; LSD at P = 0.05, = 3.98 q; CV = 27%), and further it was compatible with the half dose, which resulted in no additional increase. Full dose was as good as the half dose in the dry land cultivation, full dose giving 19.0 q ha<sup>-1</sup> and half dose giving 20.5 q ha<sup>-1</sup>. Because the benefit from bacterization is substantial it seemingly dispenses away the application of chemical fertilizers. Does this mean partial or complete replacement? Can bacterial cultures act as an analogue of chemical fertilizers? Compounds like gibberellins and conactins elaborated by the inoculant bacteria<sup>4</sup> are likely to insure a healthy plant stand, full of vigour drawing adequate nutrients needed for growth and production from the soil. But, whether this kind of bacterization

alters the microbial equilibrium to such an extent that nutrients are helped out from the soil or atmosphere to the agronomic benefits is largely undetermined. Incorporation of additional components into the cultures needs confirmation in a few more trials on crops. The newly formulated bacterial fertilizers on this design are currently under evaluation for their agronomic utility. Once the utility is established, the development of technology can be perfected.

### Varietal Reaction to the Sheath Rot of Rice (*Acrocyndrium oryzae* Saw)

Sheath rot of rice caused by *Acrocyndrium oryzae* Sawada has been reported from Japan<sup>1</sup>, Thailand<sup>2</sup>, few countries in South East Asia<sup>3</sup> and India (Tamil Nadu and Hyderabad)<sup>4-5</sup>. The disease was noticed in a number of varieties in all seasons at the Paddy Breeding Station, Coimbatore. The present study was aimed to assess the reaction of some of the newly released and improved varieties to sheath rot under field condition.

Rice plants at booting stage in one metre square at random were examined, the number of infected and healthy plants and tillers noted and the percentage of disease incidence worked out. Dark brown to chocolate brown spots on upper sheaths resulting in either partial or incomplete emergence of the panicle and seed sterility are the chief symptoms of the disease. Almost all the grains in a sheath rot affected panicle invariably become brown in colour. The reaction of the varieties is given below:

Annapoorna (40.5); RP 4-14 (IET 2234) (33.3); Kannaki (28.5); Soorya (26.0); Cauvery (22.0); 6543 (20.0); ADT 30 (17.2); Jaya (16.8);

Manna (15-4); Kanna (15-4); 6547 (16-5); ADT 51 (15-4); Pennal (15-4); IR 26 (15-0); Kanchi (15-0); Kanchi (11-0); IR 20 (10-0); IR 5 (10-0); Sona (1ET 1991) (10-0); Bhavani (10-0); Valpar (10-0); Mala (9-6); Suhashini (9-6); Annapurna (7-2); IR 24 (7-2); IET 2222 (7-2); Tapochchi (5-0); Deegewoogen (5-0); IR (4-8); Basumathi (3-0); Chandina (2-4); Jayanthi (2-4); Kumar (2-4); Sigadis (1-0); Kanto (1-0); Tella hamsa (1-0); TKM 6 (1-0); TN 1 (1-0).

From the foregoing it can be seen that sheath rot, till now considered a disease of minor importance and unknown in Tamil Nadu, is coming into prominence. Annapoorna was comparatively more susceptible, while T.N.1, TKM 6, Tella hamsa, Kanto and Sigadis showed least susceptibility.

#### Occurrence of a New Disease on Grape Seedlings Caused by *Phytophthora nicotianae* var. *parasitica* (Dastur.) Waterhouse from India

Since 1972, severe outbreaks of a 'damping off' disease of hybrid grape seedlings have been observed at the Indian Institute of Horticultural Research, Hessaraghatta.

The disease symptoms appear as light brown, irregular water soaked areas on the collar region of the young seedlings, which soon enlarge and coalesce forming distinct depressed lesions and ultimately the seedlings collapse. Bleaching of the leaves is another initial characteristic symptom of this disease.

Microscopic examination of affected tissues from diseased seedlings repeatedly showed the presence of abundant Papillate sporangia and non-septate mycelium. The sporangia on germination produced biflagellate zoospores, characteristic of the genus *Phytophthora*. Based on the morphological and cultural characters, the fungus was identified as *Phytophthora nicotianae* var. *parasitica* (Dastur.) Waterhouse. On artificial inoculation, this fungus was found to be pathogenic on seedlings of Aster, Carnation, Bougainvillea, Petunia and Hibiscus. In addition, green fruits of tomato, okra, capsicum,

brinjal, bean, coconut, jack and guava were also found to be susceptible.

#### Addition to the Host Range of the New Strain of Brinjal Mosaic Virus

In the earlier report (Naqvi and Mahmood<sup>1</sup>) a new strain of brinjal mosaic virus (BMV) has been reported. On further studies, however, some Solanaceous plants were proved to be additional hosts of the virus. These are: *Solanum aculeatum* St. Lag., *S. aviculare* Forst., *S. hispidum* Pers., *S. hybridum* Jacq. and *S. mammosum* L. All the above hosts produced characteristic symptoms and the virus could be recovered on back inoculation to the test plants of *S. melongena* L. var. *Pusa Purple Long*.

#### Some Observations of Gamma Irradiation on Growth and Flowering of Tuberose Bulbs

The Department of Horticulture, Mahatma Phule Krishi Vidyapeeth, Rahuri, has initiated a programme of irradiation research on ornamental crops with a view to evolve improved strains through mutation. The present observations include data on dose-response of tuberose flowering to radiation. Some of the somatic effects are also included in this short report. Desai<sup>1</sup>, while studying effects of irradiated bulbs of tuberose with acute doses of gamma rays, reported that bulbs survived upto 2.5 Kr.

150 bulbs of single tuberose were irradiated at Bhabha Atomic Research Centre, Trombay, with 0.5 Kr., 2.5 Kr. and 3.5 Kr. doses and planted on 20-6-1974 in the horticultural Nursery of the Department of Horticulture, at Rahuri. About 20-25 bulbs of equal size were irradiated with each dose.

Data were recorded in date of appearance of first flower stalk, length of stalk at first flowering, date of first flower opening, length of flower-stalk, girth of stalk, length of internodes and the number of leaves when first flower stalk emerged.

From Table I it is seen that the gamma dose of 0.5 Kr. gave one desirable mutant with bolder

TABLE I  
Effect of gamma irradiation on growth and flowering of tuberose

| Gamma dose (Kr) | No. of days required for first flowering   | Length of stalk at first flowering (cm) | No. of days required for first opening of flower | Length of flower stalk (cm) | Girth of flower stalk (cm) | Length of internodes (cm) | No. of leaves when 1st flower stalk emerged | Other observations  |
|-----------------|--|---|--|-----------------------------|----------------------------|---------------------------|---|---|
| Control         | 150  | 40-42                                   | 156  | 70                          | 2.5-3                      | 8-10                      | 15.00                                       | ..  |
| 0.5             | 140  | 50-58                                   | 145  | 73-90                       | 1.5-4.0                    | 8-14                      | 13-30                                       | One mutant gave bolder flowers compared to control plants. Flower tube length was 5 cm compared to 4.0-4.5 cm of control and other doses. Flower diameter was 4.1 cm compared to 3.5-4 cm in control and other doses. |
| 1.5             | 140  | 42-50                                   | 148  | 69-75                       | 1.5-4.0                    | 10-14                     | 11.20                                       | 4-5 stalks were found bifurcated. Leaves with ivory coloured midrib. 3 flowers at one place instead of 2 in control and other plants.   |
| 2.5             | Very poor sprouting of bulbs. 4 out of 25 bulbs sprouted upto 5 months after planting. |   |  |                             |                            |                           |   |   |
| 3.5             | No. sprouting of bulbs.  |   |  |                             |                            |                           |   |   |

flowers compared to control plant and plants from bulbs treated with other doses. As reported by Desai the abnormalities like bifurcated stalks, ivory coloured midrib were observed in bulbs treated with 1.5 Kr gamma dose. The higher doses like 2.5 Kr and 3.5 Kr proved to be more or less lethal for sprouting tuberose bulbs.

### Unstable Haemoglobin

Unstable haemoglobin syndromes comprise of a group of inherited disorders characterised by haemolytic disease of varying severity. In view of paucity of reports in Indian literature, tests were conducted to detect this abnormality in 10 normal persons and 31 patients with different haematological disorders attending the Department of Haematology of the School of Tropical Medicine, Calcutta.

In control subjects, the range of heat-labile haemoglobin was 0 to 1.8%. Series of estimations

from blood samples, preserved in A.C.D. solution, revealed a gradual rise of unstable haemoglobin level reaching 4% on the 10th day and thereafter a fall reaching normal level after two weeks.

Two cases of unstable-haemoglobin syndromes were detected; One had 32% of unstable haemoglobin with mild haemolytic anaemia and the other with 12.5% of unstable haemoglobin associated with iron deficiency anaemia.

Excess amounts of heat-labile haemoglobin upto 12% range were detected in 10 out of 16 cases with Haemoglobin-E-Thalassaemia disease. It is probably from the excess alpha chains synthesised by the reticulocytes and young red cells.

Heat-labile haemoglobin was not detected in other haematologic disorders such as, iron deficiency anaemia, glucose-6-phosphate dehydrogenase deficiency, idiopathic thrombocytopenic purpura and myelophthisic anaemias.

### Occurrence of *Pythium butleri* Subr. in *Amaranthus tricolor* var. *gangeticus* (Linn.) F and P.

A severe 'damping off' disease of amaranthus [*Amaranthus tricolor* var. *gangeticus* (Linn.) F & P.] seedlings was observed in November 1973, around

Hebbal, Bangalore, the disease was noticed when the seedlings were in 4-6 leaf stage. Affected plants showed rotting of the stem at ground level. In the initial stages, water-soaked zone at basal portion was noticed which later turned brown and soft. The infected portion got constricted resulting in toppling of the seedlings. The seedlings remained in this condition for one or two days and later died. The disease was observed to occur in patches. Repeated isolations from the diseased seedlings in culture yielded a pythiaceus fungus.

For pathogenicity studies, the fungus, cultured on corn-meal agar, was mixed with sterilized soil in plastic trays. A week later, surface sterilized amaranthus seeds were sown into them. Both pre and post-emergence 'damping off' was noticed at germination time in inoculated soil. Out of 300 seeds sown 268 seeds germinated in uninoculated soil as against 64 in inoculated soil. All the seedlings in inoculated soil died in a fortnight's time. The pathogen was reisolated from such infected seedlings. The fungus was identified at Centraal-

bureau Voor Schimmelcultures, Baarn, Netherlands, as *Pythium butleri* Subramanian. The culture has been deposited in the culture collection of Department of Plant Pathology, U.A.S., Bangalore, and has been given accession No. 101.

The fungus is known to attack tobacco, ginger, papaya, chille<sup>1</sup>, maize<sup>2</sup>, and torai<sup>3</sup>. However, there is no record of this fungus on amaranthus and this is a new host record.

Grateful thanks are due to Director and Dr. R. A. Samson of CBS, Netherlands, for identification of the fungus, Dr. H. C. Govindu, Sr. Professor and Head of the Department, for facilities, Dr. N. P. Patil, Director of Research, for encouragement.

## REVIEWS AND NOTICES OF BOOKS

### Annual Review of Physical Chemistry (Vol. 25).

Edited by H. Eyring, C. J. Christensen and H. S. Johnston. (Annual Reviews, Inc., 4139 Camino Way, Palo Alto, California 94306). Pp. 566. Price : U.S.A., \$ 12.00 ; Elsewhere \$ 12.50.

The book contains 19 chapters on a variety of topics in physical chemistry. Starting from the history of physical chemistry in Denmark which forms the first chapter, the book covers several subjects of current interest and development, e.g., laser light scattering from liquids, laser-induced chemical reactions, lipid phases, mechanism of ion-transport in lipid membranes, magnetic circular dichroism to mention a few.

In the chapter on the history of chemistry in Denmark, the author Prof. T. A. Bak describes some important discoveries made in Denmark but it appears as though nothing much has been achieved after 1947.

Studies on lipid-water systems with particular emphasis on X-ray scattering have been described thoroughly by Luzzati and Tardieu. Structures of the phases are illustrated with the help of impressive diagrams.

The instrumentation, the general theory and the applications of the method of magnetic circular

dichroism are discussed and the literature coverage is from 1960 to 1973.

Laser light scattering studies as applied to macromolecules bacterial motion, gels, collision induced anisotropies and rotational motion of molecules in liquids have been described. An account of infrared- and ultraviolet-laser induced reactions, selective two step reactions and laser temperature jump relaxation experiments is given. The areas of vibrational and rotational relaxation in the ground state of small molecules using the laser devices and of the molecular trajectory calculations have been covered. Recent developments relating to the understanding of molecular collision have been given. The basis of the electrical excitability of nerve cells has been discussed in the chapter on excitable membranes. Time domain electron paramagnetic resonance, electron-nuclear double resonance of free radicals in solution and of proteins and electron-electron double resonance in organic systems have been exhaustively reviewed. Experimental techniques, their objectives and the scope for studies on gaseous negative ions, theory of liquid mixtures of non-electrolytes and the spectroscopy of linear polyenes have been described. Vibration relaxation in condensed media and its

role in unimolecular reactions and molecular luminescence, the present state of the subject of oscillatory chemical reactions, the theory of  $\pi$ -molecular charge transfer crystals and their magnetic, optical and electric features are covered. Developments in the field of rotation and rotation vibration pressure broadened spectral line shapes have been described with particular emphasis on the work after 1967. A critical analysis of the controversies in the literature on polymer statistical mechanics has been made.

At the end cumulative indices of the contributing authors and the chapter titles of volumes 21 to 25 of the series are given.

The overall coverage of the literature is quite up-to-date and the section of the topics is, in general, of considerable interest to physical chemists.

C. L. KHETRAPAL.

#### Quantum Mechanics in Chemistry (2nd Edn.).

By Melvin W. Hanna. (W. A. Benjamin Inc., Advanced Book Programme, Reading, Mass.), 1973. Pp. xv + 260. Price not given.

This book is an attempt to introduce to the students of chemistry certain aspects of quantum mechanics that should be known to every chemist. However, none of these aspects is discussed in full and the author has very rightly confessed in his preface that students using this book need to spend considerable time in the library reading other works. Although most chapters are written with greater clarity than those in the previous edition there is much to be done yet within the limits of this book.

In the chapter on spectroscopy, the author has discussed the interaction of radiation with atom or molecule but refrained from discussing the time-dependent perturbation theory by saying that the latter is mathematically more complicated than the time-independent perturbation theory. But, I should imagine that a simplified quantitative treatment of this topic should not have been beyond the scope of this book. This aspect of quantum mechanics is very important because it forms the basic foundation of spectroscopy.

In the chapter on molecules and the chemical bond, the symbols  $\sigma$ ,  $\pi$ ,  $\delta$ , etc., and  $\Sigma$ ,  $\Pi$ ,  $\Delta$ , etc., are not explained while they are freely used in several pages.

Chapter 9 is readable and interesting and provides enough material to build a foundation in the chemical aspect of the magnetic resonance spectroscopy.

This book can be recommended as a companion volume in physical chemistry for the students of chemistry at the University level in India.

## CURRENT SCIENCE

*Fortnightly Journal of Research*

Issued on the 5th and 20th of each month

### IMPORTANT NOTICE TO SUBSCRIBERS OF THE JOURNAL

As you are aware CURRENT SCIENCE has been coming out regularly on the due dates as above with the kind co-operation of you all.

On account of the sharp increase in the cost of quality paper used for the journal, increase in rates of block making materials, increase in postal rates and the increase in the establishment charges it has become impossible for the Association to issue the Journal, unless the subscription rates are put up.

The Working Committee of the Association has reluctantly decided at its last meeting, to enhance the subscription of CURRENT SCIENCE with effect from 1st January 1975 for institutions :

India Rs. 84/- Foreign Rs. 150.00 \$ 20.00 or £ 8.0.0

The subscription rates for individual subscribers however will remain the same as now.

The continued co-operation of our subscribers is requested.

# FISSION TRACK AGES AND URANIUM CONCENTRATION OF APATITES OF DIFFERENT ROCKS OF SOUTH INDIA

NAND LAL AND K. K. NAGPAUL

*Department of Physics, Kurukshetra University, Kurukshetra 132 119*

AND

M. K. NAGPAL

*Department of Physics, National Defence Academy, Poona*

## ABSTRACT

The uranium concentration and ages of apatite grains of various rocks of South India have been measured by fission track technique. The ages range from 100 m.y. to 730 m.y. whereas uranium concentrations vary from 0.5 to 23.8 atom/million atoms of the apatite mineral. The ages agree well with the Deccan volcanic and Indian Ocean Cycle activities.

## INTRODUCTION

THE fission track technique of dating the minerals is a promising tool for geochronological studies. Since the discovery of track etch technique by Fleischer and Price<sup>1</sup>, Nagpaul *et al.*<sup>2</sup>, and Nand Lal *et al.*<sup>3</sup> dated some of the Himalayan granites, Bundelkhand granites<sup>4</sup> and alkaline rocks of India<sup>5</sup> by 'in situ' apatite measurements. The present report on South India is in continuation of the same. The results have been discussed in the light of other isotopic age data available for the region.

## EXPERIMENTAL PROCEDURE AND RESULTS

Transparent sections of about 1 to 2 cm<sup>2</sup> area and 100–200 micron thick rock specimen were prepared by polishing successively with 800, 1200,

1500 mesh of aluminium oxide abrasive and finally with 8 micron diamond paste. They were etched with 5% HNO<sub>3</sub> at about 25° C for 30–50 seconds to reveal the fission tracks in apatite grains. Measurements of fossil and induced densities were carried out by usual procedures described elsewhere<sup>2</sup>. No observations were made (i) when grain size was very small (< 50 microns), (ii) there was non-uniformity of track density in the grain, (iii) near the grain boundary. The thermal neutron flux  $\phi$  was measured by counting  $\sim 10^4$  tracks in the uranium loaded glass sample irradiated simultaneously with the rock sections. The age T and uranium concentration  $C_w$  calculated with the following relations are given in columns 6 and 9 respectively in Table I.

TABLE I

*Fission track ages and uranium concentration in apatites*

| S. No. | Name and Location of Rock  | No. of analysis made | Fossil track density ( $\rho_g$ ) $\times 10^6/\text{cm}^2$ | $\rho_g/\rho_i$ | Observed fission track age (million years) | Track length reduction % (corresponding density reduction) | Corrected f.t. age (million years) | U-conc. atom/ $10^6$ atom | Total neutron dose $\times 10^{16}$ |
|--------|--|----------------------|---|-----------------|--|--|------------------------------------|---------------------------|-------------------------------------|

*a* Annealing correction to these ages was not possible.

\* Uncorrected ages.

$$T = 6.57 \times 10^9 \ln (1 - 9.25 \times 10^{-15} \frac{\rho_s}{\rho_i} \phi, \text{ yrs.})$$

$$C_x = 4.0 \times 10^8 \rho_i \phi \text{ atom/atom}$$

where  $\rho_s$  = fossil track density

$\rho_i$  = induced track density

$\phi$  = integrated thermal neutron dose.

In order to assess the geological annealing, *in situ* length measurements of fossil tracks were made<sup>6</sup> and compared with the length of induced fission tracks. The method for applying the corrections

has already been discussed in the literature<sup>7</sup>. The corrected ages are given in column 8 of Table I. The corrections to some of the ages could not be made because (i) fossil track density  $< 10^6/\text{cm}^2$ , does not satisfy TINT formation conditions<sup>6</sup> as in sample No. 10. (ii) Number or size of apatite grains, though enough for age determinations, was not sufficient to give statistically significant number of TINTS. The errors given with the individual values are only the statistical counting errors com-

puted from fossil and induced track densities. The mean values are given with one standard deviation. Measurements of fossil and induced track densities on the same grain, no doubt eliminates the error due to the non-uniformity of uranium on the surface, but the variation of the uranium in the volume may give rise to some errors in the age. This factor along with the uncertainty in the neutron dose measurement constant, have not been quoted with the ages. The uranium content in apatite shows large dispersion. Even in the same section it varies from grain to grain.

### DISCUSSION

In general, the ages of Andhra Pradesh witnessed the influence of Eastern Ghat belt which runs from Cuttack to Bezwada, attaining the maximum width in Cuttack-Ganjam region<sup>8</sup>. The dominant trend of the belt in Andhra Pradesh is NE-SW, with local variation due to cross folding<sup>9-11</sup>. It is mainly composed of sub-parallel alternating layer of khondalites and their variants, granite gneisses and charnockites<sup>8</sup> (pyroxene granulite). On the basis of available geological and geochronological data, the following probable sequence of events can be assigned to this belt<sup>8,12,13,14</sup>.

(i) Deposition of pelitic sediments in an extensive geosyncline.

(ii) Folding and metamorphism of the sedimentary rocks to form khondalites (~1600 m.y.).

(iii) Emplacement of charnockites and granites (~1300-1500 m.y.).

(iv) Metamorphism, folding and uplift of the Eastern Ghats (~700-450 m.y.) known as Indian Ocean cycle.

The fission track ages of different apatites (Andhra Pradesh) range from 360 to 600 m.y. (sample Nos. 1 to 9). These ages which generally respond to last metamorphic activity due to high sensitivity of fission tracks against thermal variations support the last, i.e., Indian Ocean cycle episode (~700-450 m.y.)<sup>13</sup>. The mineral under investigation is apatite which is most temperature sensitive (as far as fission tracks are concerned), further strengthen the susceptibility of these fission track ages to the last thermal event. These fission track ages of apatites of Andhra Pradesh, also fall in the range of fission track ages of minerals muscovite, biotite and apatite of Nellore mica belt<sup>15</sup>.

The age ( $580 \pm 60$  m.y.) of Khamam Dist. is comparable with the isotope age of Galena (650-770 m.y.)<sup>12</sup>. It is also consistent with the other fission track ages made on zircon ( $518 \pm 17$  m.y.) and apatite ( $571 \pm 37$  m.y.) minerals of pegmatitic origin<sup>16</sup> from the nearby regions.

The age  $100 \pm 10$  m.y. of hornblende synetite of Phanai Mata Hill indicates that it lies within Deccan Volcanic province. On the basis of this result, it should be placed well within Mesozoic.

The fission track age  $670 \pm 30$  m.y. of granite from Tamil Nadu (sample No. 11) is corroboratable with 700 m.y. event, i.e., Indian Ocean cycle.

Karnataka region has undergone quite a number of orogenic metamorphic cycles, the effect of which is found to be increasing towards the south, accompanied by some igneous activity (pegmatization, granitization, and alkaline gabbro syenite complex)<sup>8</sup>. The fission track ages  $730 \pm 80$  and  $760 \pm 120$  m.y. of sample Nos. 12 and 13 are probably due to latest thermal event during Indian Ocean cycle or due to some later igneous activity. Due to the low annealing temperature, the age  $730 \pm 80$  of apatite is lower than the corresponding fission track age of hornblende ( $840 \pm 33$  m.y.) from the same region<sup>17</sup>.

### CONCLUSION

From the above data it may be concluded that : most of the fission track ages of apatite grains from different rocks of South India corroborate the Deccan Volcanic and Indian Ocean cycle.

### ACKNOWLEDGEMENT

We are thankful to Council of Scientific and Industrial Research, New Delhi and PL-480 NBS (G) 182 research grant for financial assistance.

## OXOTITANIUM(IV) COMPLEXES WITH 2-OH-ACETOPHENONE OXIMES

N. S. BIRADAR,\* M. D. PATIL AND V. B. MAHALE

*Department of Chemistry, Karnatak University, Dharwar 589 003*

## ABSTRACT

Oxotitanium (IV) complexes have been prepared by treating oxotitanium (IV) perchlorate with 2-OH-acetophenone oxime in aqueous alcohol medium. The complexes are orange-yellow to orange-red in colour. These complexes are characterised by elemental analysis, molecular weight, conductometric and spectral data. Five coordinate trigonal bipyramidal structure has been suggested for these complexes.

## INTRODUCTION

COMPLEXES with oximes have been the subject-matter of a large number of investigators<sup>1,2</sup>. This paper deals with a study of complexes of oxotitanium (IV) with the following ketoximes (I-V).

## EXPERIMENTAL

2-OH-acetophenone and substituted 2-OH-acetophenones were prepared by known method<sup>3</sup>. Hydroxylamine hydrochloride was of reagent grade. The ketoximes were prepared by heating a solution of 1 g of 2-OH-acetophenone, 1 g of hydroxylamine hydrochloride and 2 g of sodium acetate in 10 ml of ethanol on a steam bath for an hour. The ketoximes thus prepared were recrystallised from aqueous ethanol. Titanyl perchlorate was prepared according to the method reported in the literature<sup>4</sup>.

Complexes were prepared by reacting oxotitanium (IV) perchlorate (10 m mole) dissolved in aqueous ethanol with ketoxime (22 m mole) in aqueous ethanol with vigorous shaking. Sufficient time was allowed for the precipitate to settle. The complex formed was filtered, washed with aqueous ethanol and dried at 110° C.

The complexes were analysed for titanium and nitrogen contents by standard methods. The molecular weights of the complexes in nitrobenzene were determined by the Beckman freezing point method. The infrared spectra of the complexes and the ligands in nujol mull were recorded on Perkin-Elmer-337 in the region 4000-400 cm<sup>-1</sup>.

## RESULTS AND DISCUSSION

The elemental analysis of the complexes (Table I) show that oxotitanium (IV) perchlorate reacts with ketoxime in 1:2 ratio, losing two of its perchlorate ions. The complexes are orange-yellow to orange-red in colour and highly soluble in common organic solvents. Molecular weights of the complexes determined in nitrobenzene agree well with the empirical formulae and the monomeric nature in nitrobenzene. These complexes show negative test for perchlorate ion. The molar conductance values in nitrobenzene at 10<sup>-3</sup> M fall in the range 0-3.0 ohm<sup>-1</sup> cm<sup>2</sup>/mole, indicating that these are nonelectrolytes in nitrobenzene.

**Infrared Spectra.**—The important infrared frequencies are given in Table II along with their assignments. The IR spectra of the ligands under investigation show two bands, one around 3340 cm<sup>-1</sup> and other around 2600 cm<sup>-1</sup>; the former is broad with high intensity and the latter is weak. The band around 3340 cm<sup>-1</sup> is due to intermolecular hydrogen bonded -OH, and that around 2600 cm<sup>-1</sup> to intramolecular hydrogen bonded -OH. In case of salicylaldoximes the band due to intramolecular hydrogen bonded -OH is observed around 3200 cm<sup>-1</sup>. This shows that the intramolecular hydrogen bonding in ketoximes is stronger than that present in salicylaldoximes. In the complexes the band at 2600 cm<sup>-1</sup> vanishes and the band around 3340 cm<sup>-1</sup> is retained, which indicates the presence of intermolecular hydrogen bonding -OH.

In view of the previous assignments<sup>5,6</sup> the high intensity band in the region 1640-1630 cm<sup>-1</sup> in ligands is attributed to C=N stretch. In complexes this band is observed in the region 1550-1530 cm<sup>-1</sup>. This shift towards the lower frequency indicates the coordination of the C=N group to oxotitanium,

through nitrogen and lowering of the bond order of the carbon to nitrogen link. The strong band in the region 1280–1300 cm<sup>-1</sup> of the ligands, due to the phenolic C–O is found in the region 1300–1310 cm<sup>-1</sup> in the complexes. This is indicative of titanium-oxygen bond formation with oxygen of the *o*-OH group of the ketoximes.

It is evident from the previous reports<sup>7,8</sup>, that a discrete Ti=O group in the complexes gives a sharp band in the multiple bonded metal-oxygen stretching region, 1100–900 cm<sup>-1</sup>. In all the complexes studied, a high intensity broad band is observed in the region 1040–1020 cm<sup>-1</sup>. This is attributed to the Ti=O stretching vibration,

The metal-nitrogen bands are reported to occur in the range 600–500 cm<sup>-1</sup> for the Schiff base<sup>9</sup> and oxime<sup>1</sup> complexes. In view of these assignments, we have assigned the band in the region 560–520 cm<sup>-1</sup> to (Ti–N) vibration. The presence of the only one band in these complexes suggests that the complexes exist in the *trans* form. The region 500–400 cm<sup>-1</sup> is attributed to M–O stretching vibrations<sup>10,11</sup> in the complexes. In the light of these observations a medium intensity band found around 400 cm<sup>-1</sup> is assigned to (M–O) vibration.

All these observations suggest that these oxotitanium (IV) complexes have coordination number five. On the basis of the previous literature<sup>12</sup> a

trigonal bi-pyramidal structure with intermolecular hydrogen bonding is proposed for the present series.

### PREVALENCE OF SOLUBLE COMPLEMENT FIXING (SCF) ANTIBODY TO JAPANESE ENCEPHALITIS (JE) VIRUS IN CASES OF JE VIRUS INFECTION

JAGDISH RAI,\* N. P. GUPTA\*\* AND S. N. GHOSH†

#### ABSTRACT

Serial samples of human sera belonging to confirmed cases of Japanese encephalitis (JE) virus infection were studied for the presence of antibody to soluble complement fixing (SCF) antigen of JE virus.

All the convalescent phase sera (39) out of a total of 44 sera tested, were positive for JE SCF antibodies whereas all the acute phase sera (5) were negative for these antibodies. There was complete correlation between results of complement fixation (CF) and Agarose gel diffusion (AGD) tests with JE SCF antigens. Use of JE SCF antigen as a useful reagent for specific serodiagnosis of JE virus infection by CF and AGD tests is suggested.

FALKLER *et al.* (1973) detected SCF antibodies exclusively in sera of secondary dengue cases in convalescent phase of the infection. They were unable to detect SCF antibodies in acute and primary convalescent phase sera of patients with dengue infection.

Presence of SCF antibodies in human sera in Japanese encephalitis (JE) virus infection has been demonstrated recently (Rai *et al.*, 1975) by complement fixation (CF) and Agarose gel double diffusion (AGD) tests. However, only a limited

number, mostly secondary type convalescent phase sera were found to be positive for JE SCF antibodies.

In view of the absence of correlation between HI, CF and/or neutralizing antibodies and SCF antibodies, more sera from confirmed cases of JE virus infection were tested.

#### MATERIAL AND METHODS

*Viruses*.—JE Virus (VRC Strain P 20778) plaque purified in Vero cells was used for preparation of JE SCF antigen. SCF antigens of West Nile (Strain G 22886), DEN-1 (Hawaii), DEN-2 (Strain P 23085 and TR 1751), DEN-3 (Strain 633798), DEN-4 (Strain 642069 and 611319) and Chikungunya (CHIK strain 634029) viruses were also prepared.

\* Lt. Col. Jagdish Rai, AMC, Virus Section, Armed Forces Medical College, Poona-1.

\*\* Dr. N. P. Gupta, Director, Virus Research Centre, Poona-1.

† Dr. S. N. Ghosh, Assistant Director and Head, Division of Immunology, Virus Research Centre, Poona-1.

**SCF Antigens.**—SCF antigens were prepared from the infected mouse brain. A 20% suspension of infected brains of the suckling mice in 0.02 M Tris HCl buffer (pH 8.2) was centrifuged at  $105,000 \times G$  for 4 hours and upper third of the supernatant fluid was used as SCF antigen. The control SCF antigen was prepared in a similar manner from the brains of normal infant mice inoculated with plain normal saline (0.02 ml each, intracerebrally).

**Immune Peritoneal Fluids.**—Mouse hyperimmune peritoneal fluids to crude mouse brain suspensions of JE (P 20778), WN (strain G 22886), DEN-1 (Hawaii), DEN-3 (Strain 633798) and Chikungunya (CHIK) viruses and to SCF antigens of these viruses were prepared in adult female mice according to the method described by Brandt *et al.* (1967).

**Human Sera.**—The sera used in the present study were collected during an outbreak of Japanese encephalitis (JE) virus infection in North Arcot District of Tamil Nadu State, India in 1955 and 1956 and stored at Virus Research Centre, Poona. A total of 44 sera belonging to 14 cases of JE virus infection confirmed clinically and serologically (by HI, CF and/or neutralization tests) as reported earlier (Webb and Pereira, 1956 and Work and Shah, 1956) were available. The sera had been kept all these years at  $-20^{\circ}C$ . These 44 sera were comprised of serial samples, collected during acute and convalescent phases of illness. Sera collected within 7 days after the onset of symptoms were referred to as acute samples whereas those collected after 8 days were considered as convalescent sera.

**Complement Fixation Test.**—CF tests were done by employing the procedure described by Casals (1967) adapted to micro-techniques in 'U' plates employing 4–8 units of SCF antigen per test volume (0.025 ml).

**Agarose Gel Diffusion (AGD) tests.**—Double diffusion immunoprecipitation tests were performed on  $7 \times 2.5$  cm microscopic slides employing 1% agarose in 0.05 M borate saline (pH 9.0). Merthiolate (1:10,000) or sodium azide (1:1000) was used as preservative. About 3.0 ml melted agarose (1%) was sufficient for each slide. Wells were cut in hexagonal pattern (one central well having six peripheral wells) with 4 mm diameter and 8 mm centre to centre distance. SCF antigens, standardized to 256 units, and normal antigen were placed in central wells and the human sera in the peripheral wells.

## RESULTS

Clinico-serological classification of the sera tested and results of CF and AGD tests with JE SCF antigen are given in Table I. These results show that all the convalescent phase sera (39) were positive for JE SCF antibodies in CF and AGD tests. The earliest time of detection of JE SCF antibodies was 9 days after the onset of symptoms. Out of these 39 sera positive for JE SCF antibodies 7 sera were of monoreacting type (antibodies against JE virus only) and 32 sera were of cross reacting (secondary) type, showing cross reactions with sucrose acetone extracted mouse brain (SAMB) antigens of other group B arboviruses also. All the 5 acute phase sera were negative for JE SCF antibodies in CF and AGD tests. There was no correlation between antibodies to SAMB antigens and SCF antibodies. Some of the sera which had high HI and CF antibodies to SAMB antigens had low JE SCF antibody titres and *vice versa* too. In one case of late convalescent phase (352 days after onset of symptoms) there were no detectable HI and CF antibodies to SAMB antigens whereas JE SCF antibodies were detected in CF and AGD tests. These 39 sera positive for JE SCF antibodies did not react with SCF antigens of West Nile (WN), dengue (DEN 1-4) and Chikungunya (CHIK) viruses and normal antigen in CF and AGD tests.

## DISCUSSION

JE SCF antibodies were detected in all the convalescent phase sera (39), whether nonreacting (1) monoreacting (7) or cross reacting (31) types. On the other hand all the acute phase sera (5), whether nonreacting (2) or monoreacting (2) or cross reacting (1) types were negative for JE SCF antibodies. There was complete correlation between results of CF and AGD tests with JE SCF antigen. All the 39 sera showing JE SCF antibodies in CF tests were also positive in AGD tests with JE SCF antigen, but none of them reacted with SCF antigens of WN, DEN (1-4) and CHIK viruses and normal antigen in CF and AGD tests. These findings have demonstrated a considerable degree of specificity and sensitivity of JE SCF antigen and antibody in CF and AGD tests.

It is too premature to comment on the role of SCF antigen and the significance of SCF antibody in JE virus infection. However, the specificity and sensitivity of JE SCF antigen seen in the serological reactions (CF and AGD tests) suggests that it could be employed as a useful reagent for specific serodiagnosis of JE virus infection.

## LETTERS TO THE EDITOR

**EFFECT OF ADDED COMPLEXING AGENTS AND BASES ON THE RATE OF OXIDATION OF  $\alpha$ -HYDROXY ACIDS BY LEAD TETRA ACETATE**

The rate of cleavage of 1, 2 diols by lead tetra acetate (LTA)<sup>1</sup> was found to be enhanced by the addition of pyridine or acetate ions<sup>2</sup>. The oxidation of hydroxy acids by LTA has formed the subject of recent investigations<sup>3,4</sup>. We present here the results of our studies on the effect of added bases and complexing agents on the rate of these reactions. Lactic acid has been chosen as the typical substrate. The oxidation of lactic acid by LTA, is of a total second order being first order with respect to the substrate and LTA. The reaction is profoundly susceptible to the influence of added salts especially the acetates (Table I).

Pyridine, quinoline, 2, 2'-dipyridyl and 1, 10-phenanthroline when used as complexing agents/bases bring about considerable rate acceleration (Table II). In fact, there seems to be a linear dependence between the rate and the concentration of the added reagent. Separate experiments show that under the reaction conditions employed, pyridine, quinoline, 2, 2'-dipyridyl and 1, 10-phenanthroline were not oxidised by LTA in any significant measure,

It is to be noted that the bidentate ligands 2,2'-dipyridyl and 1, 10-phenanthroline have a more pronounced effect than pyridine and quinoline for a given concentration.

A mechanism involving the formation of a Pb (IV)-hydroxy acid monoester (by a nucleophilic displacement of an acetoxy group by the hydroxyl function of the acid), followed by the rate determining decomposition of the monoester, to products has been proposed for this reaction. Alternatively, the mono acetoxy ester could, in a slow step interact with an adjacent—COOH group, to give a cyclic ester which could then decompose to give the products. It is highly probable that the added complexing reagents are functioning, more as bases catalysing the reaction, rather than as complexing ligands. For, in the proposed mechanism, an added

base can facilitate a proton removal either in the slow decomposition of the monoester or aid the formation of the cyclic ester. Base catalysis in the LTA oxidation<sup>5-6</sup>, of 1, 2-diols and formic acid lends further credence to this view. It is also possible that pyridine displaces the acetate, to generate a more reactive Pb (IV) compound<sup>2</sup>. A lead tetraacetate pyridinate has actually been isolated<sup>7</sup> and is reported to have the structure.

This has been shown to have a greater oxidising power than LTA itself. Complexes of this type can be envisaged for the other ligands. In the case of 2, 2'-dipyridyl and 1, 10-phenanthroline, a first order dependence on [ligand] is observed. This is not unexpected as 2, 2'-dipyridyl and 1, 10-phenanthroline are better complexing agents than pyridine or quinoline.

### METAL CHELATES OF $\alpha$ -BROMOACETO- ACETANILIDE

AMONG the metal chelates of  $\beta$ -dicarbonyl compounds, only metal acetylacetonates have received adequate attention<sup>1</sup>. Alpha substituents like nitro and diazonium, which are unstable on acetylacetonates, are stabilised in metal acetylacetonates. Synthetic advantage has also been derived through these substituted acetylacetonates<sup>2-3</sup>. Such possibilities prompted an extension of these studies to other  $\alpha$ -substituted  $\beta$ -dicarbonyl compounds. Hence this investigation on  $\alpha$ -bromoacetoacetanilide and its metal chelates.

The ligand<sup>4</sup> was prepared by adding slowly an aqueous-methanolic (1:1 by volume) solution of bromine (4%) to a stirred solution of acetoacetanilide (4 g) in normal sodium hydroxide solution (about 25 ml) until the colour of bromine persisted even after long stirring. The resulting residue was filtered, washed with water and then with a little acetone, and sucked dry.

Among the metal chelates prepared (through slight modifications of the methods generally employed for the syntheses of  $\beta$ -dicarbonyl complexes<sup>5-7</sup>), those which have been obtained pure (judged from their analytical data for metal and nitrogen) are listed in Table I.

The complexes have been further characterised on the basis of their 'Nujol mull' infra-red spectra (recorded in the 4000-650  $\text{cm}^{-1}$  region on a Perkin-Elmer 257 spectrometer). The ligand shows its  $\nu$  N-H around 3200  $\text{cm}^{-1}$ , which in the complexes is shifted to about 3350  $\text{cm}^{-1}$ , evidently due to disengagement of the N-H from intramolecular hydrogen bonding<sup>8</sup>. This shift is also construed as an evidence for the abstention of the nitrogen atom from co-ordinating to the metal, since otherwise only a depression of the N-H stretching frequency could have resulted<sup>9</sup>.

The free ligand shows absorptions at 1730 and 1650  $\text{cm}^{-1}$  due to the ketone and amide carbonyl groups respectively (*c.f.* assignments of the spectral bands of acetoacetanilide<sup>6</sup>). In the chromium complex these are respectively at 1560 and 1585  $\text{cm}^{-1}$ , showing that both the carbonyl oxygens are bonded to the metal as in metal  $\beta$ -keto-enolates<sup>5,6,10</sup>, as shown in Fig. 1. From spectral similarity it is evident that the other complexes of Table I are also of the same inner complex type-

FIG. 1. Illustration of the mode of chelation.

However the amide carbonyl frequency (amide I) is much higher in the less stable complexes than in the chromium complex; this frequency is about the same in a few complexes as in the free ligand. At least, in part, this could be due to the electron attracting  $\alpha$ -substituent, asserting its role when the metal-ligand bond is weak. Electron withdrawal by substituents is known to raise amide I frequency<sup>11</sup>. In order to gain further insight into the causes of the amide I frequency shifts in these complexes, an investigation

### LIGAND EXCHANGE IN POLYMERIZATION CATALYSIS

OFTEN, to explain the results of polymerizations catalysed by metal complexes, substitution of a ligand by a monomer molecule in the complex is suggested without sufficient proof. To explain a second-order dependence of the rate of acrylamide

polymerization on monomer concentration with aquopentamminecobalt (III) complex as the initiator, Delzenne<sup>1</sup> suggested participation of the monomer in the formation of the initiating radicals through a reversible substitution of the coordinatively bonded water molecule by acrylamide (analogous to the substitution of a ligand by N-methylacetamide<sup>2</sup> in [Co(en)<sub>3</sub>X<sub>2</sub>]X followed by photochemically induced electron transfer within the intermediate complex. We considered<sup>3,4</sup> the analogy to be inappropriate, because while there was a distinct change of colour on mixing N-methylacetamide and solution of the complex and the shifts in  $\lambda_{\max}$  values were also reported, in the case of the aquopentamminecobalt (III) complex no such colour change or change in optical density measurements were reported. Delzenne concurred with us in a subsequent private communication. In the case of diazidotetramminecobalt (III) azide also there was no significant change in the spectrum of the complex on addition of acrylamide proving that no complexation by substitution was involved<sup>3</sup>.

Recently Komoto and Ohmura<sup>5</sup> studying the oxidative polymerization of 2,6-xyleneol by amine complexes have postulated ligand exchange reaction between the copper (II) pyridine complex and the monomer which then causes initiation. In the

light of the foregoing considerations we considered such a reaction to be unlikely. The spectrum of a 0.05 M solution of the copper (II) pyridine complex was recorded in a Beckman DU 2 model Spectrophotometer (*vide* Fig. 1). Absorbance was

negligible in the region 380–500 nm, but increased to a maximum at 760 nm. The spectrum of the copper pyridine complex-2, 6-xyleneol mixture was practically the same, with the xyleneol alone showing decreasing absorbance at increasing wavelengths.

#### FIELD EFFECTS *VIS-A-VIS* SOLVENT EFFECTS IN THE ALKALINE HYDROLYSIS OF PHENYL ACETATE AND *o*-CARBOXYPHENYL ACETATE

In the alkaline hydrolysis of a series of dicarboxylic esters in aqueous DMSO and aqueous EtOH, we had observed a considerable increase in the  $k_I/k_{II}$  ratio in aqueous DMSO compared to aqueous EtOH<sup>1,2</sup>. We have now studied the alkaline hydrolysis of phenyl acetate (I) and *o*-carboxyphenyl acetate (II) in aqueous DMSO and aqueous EtOH with a view to finding out the effect of solvent on such a repulsion between an inbuilt carboxylate anion and OH<sup>-</sup> ion on the rate of saponification. The essential difference between these systems and the dicarboxylic esters previously studied is that in

the present case the inbuilt carboxylate group is in the alkyl portion of the ester.

I

II

Spectrophotometric methods were employed to follow the kinetics of the reaction. The rate constants (obtained in triplicate) were evaluated from semilogarithmic plots of  $(A_\infty - A_t)$  versus  $t$ . The kinetic results are presented in Table I. The second order rate constants were obtained from the pseudo first order rate constants. Table II provides a comparative rate picture in the various solvent mixtures.

TABLE I

Rate constants for the saponification of phenyl acetate (I) and *o*-carboxyphenyl acetate (II) at 15.5° C in aqueous solvent mixtures (v/v)

TABLE II

$k_I/k_{II}$  values in mixed solvents\*

| Solvent  | $k_I/k_{II}$ |
|----------|--------------|
| 50% EtOH | 9.7          |
| 80% EtOH | 7.4          |
| 80% DMSO | 14.0         |

\* Data from Table 1.

The general expectation of the rate enhancement in aqueous DMSO has been realised and this is naturally due to the cumulative effect of two factors : (i) poorly solvated and therefore highly reactive hydroxide ion and (ii) the increased transition state solvation in DMSO<sup>3</sup>.

The interesting finding of this investigation is the increase in the ( $k/k_{11}$ ) ratio in DMSO compared to EtOH. The decreased reactivity of *o*-carboxyphenyl acetate over phenyl acetate is due to the electrostatic repulsion between the attacking OH<sup>-</sup> ion and the carboxylate group. This is obviously much more pronounced in DMSO because of the presence of the poorly solvated hydroxide ion in aqueous DMSO. This leads to lower  $k_{11}$  values and hence the higher  $k_1/k_{11}$  ratio in aqueous DMSO. This behaviour is analogous to the one noticed in the alkaline hydrolysis of dicarboxylic esters. The operation of such a rate retarding factor is further evident if one compares this ratio in 50% EtOH and 80% EtOH. The decrease in the ratio with decrease in the dielectric constant is also in the expected direction. The decreased dielectric constant will result in the diminution of the field effect of the carboxylate anion on the reaction centre. Increased ion-pair formation is another consequence leading to a drop in the effective concentration of the carboxylate anion.

#### EFFECT OF HYDROGEN PEROXIDE ON BUFFALO MILK PROTEIN FRACTIONS

THE nutritional aspects of H<sub>2</sub>O<sub>2</sub> treated casein, whey, peptide and free amino acids, have been investigated in this laboratory<sup>1</sup>. In this paper, chromatographic studies on the composition of casein (several samples) and H<sub>2</sub>O<sub>2</sub> treated casein are compared with the electrophoretic patterns.

Buffalo casein was isolated by isoelectric precipitation<sup>2</sup>. 100 mg each of the untreated and the H<sub>2</sub>O<sub>2</sub> treated samples were hydrolysed by 6 N HCl at 120°C for 24 hours. After evaporation, the hydrolysates were made upto 10 ml in 10% isopropanol. The hydrolysates were then spotted on Whatman No. 1 filter paper and irrigated with *n*-butanol, water acetic acid (4 : 1 : 1) by employing ascending paper chromatographic technique<sup>3</sup>. The separated amino acids were identified by treatment with ninhydrin in 95% aq. acetone. Treated and untreated caseins were separately dissolved in alkali and the protein fractions were separated by both paper electrophoresis<sup>4</sup> and starch-gel electro-

phoresis<sup>5,6</sup>. The H<sub>2</sub>O<sub>2</sub> treated and the untreated whey samples were also subjected to electrophoretic separation using starch-gel.

**Results and Discussion.**—From the Chromatogram in Fig. 1, it is clear that the amino acid tyrosine is readily destroyed by the addition of

Fig. 1. 1. 0.02% (w/v) of H<sub>2</sub>O<sub>2</sub> treated casein hydrolysate. 2. 0.04% (w/v) of H<sub>2</sub>O<sub>2</sub> treated casein hydrolysate. X—untreated casein hydrolysate. 3. 0.06% (w/v) of H<sub>2</sub>O<sub>2</sub> treated casein hydrolysate. 4. 0.08% (w/v) of H<sub>2</sub>O<sub>2</sub> treated casein hydrolysate. 5. 0.10% (w/v) of H<sub>2</sub>O<sub>2</sub> treated casein hydrolysate.

0.10% H<sub>2</sub>O<sub>2</sub> (w/v) to milk. Sulphur containing amino acids are also readily affected by the gradual increase in the conc. of H<sub>2</sub>O<sub>2</sub>. Cystine bands get diffused in the chromatogram. Leucine and Iso-leucine are very much affected at high concentrations of H<sub>2</sub>O<sub>2</sub>. The Chromatogram in Fig. 1 also indicates that the amino acid composition of casein is not affected by the addition of H<sub>2</sub>O<sub>2</sub> upto 0.10% (w/v). Higher concentrations, however,

amino acids and thus reduce the nitrogen value of milk.

Electrophoretic studies as shown by starch-gel electrophoresis (Fig. 2) indicate that  $\kappa$ -casein is least affected by the addition of  $H_2O_2$  and beta-casein is moderately affected, whereas alpha-casein remains unaffected. The electrophoretic pattern of whey protein (Fig. 3) shows only two bands in starch-gel electrophoresis. Lactoglobulin is more heavily affected than lactalbumin<sup>7</sup>.

FIG. 2. Buffalo casein fraction. 1. 0.02% (w/v) of  $H_2O_2$  treated casein. 2. 0.04% (w/v) of  $H_2O_2$  treated casein. 3. Untreated casein. 4. 0.08% (w/v) of  $H_2O_2$  treated casein. 5. 0.10% (w/v) of  $H_2O_2$  treated casein.

### CHROMATOGRAPHIC SEPARATION OF Cu (II), Ni(II) AND Zn (II) IN PRESENCE OF COMPLEXING AGENTS

The presence of complexing agents along with metal ions, affect the diffusion of ions through filter paper<sup>1,2</sup>. In the present paper a rapid quantitative separation of  $Cu^{+2}$ ,  $Ni^{+2}$  and  $Zn^{+2}$  has been described in presence of complexing agents, using ascending filter paper chromatographic technique.

Chromatograms were run in glass jar (15 cm x 12 cm) having a height of 30 cm. Strips of Whatman filter paper No. 1 (3 cm x 32 cm) were used. A series of solvent systems was tried out, of which, the mixed solvent containing 90% acetone + 6% conc. HCl + 4% water (v/v) proved to be the most successful. For locating the spots, the strip was first exposed to ammonia vapour and then was sprayed with 0.1% Rubeanic acid in alcohol. Copper appears as a green and nickel as a blue spot. 0.5% Dithiazone in chloroform gave a pink spot for zinc.

The effect of the complexing agents, oxalate, tartarate and citrate was tried on the separation of Cu (II), Ni (II) and Zn (II) in three different ways. (a) by adding the complexing agents to the solvent, (b) by using filter paper impregnated with complexing agents and (c) by adding complexing

|---|-------------|--------------------------------------|------------------|------------------|-------------------------------------|------------------|------------------|
|   |             | Zn <sup>2+</sup>                     | Cu <sup>2+</sup> | Ni <sup>2+</sup> | Zn <sup>2+</sup>                    | Cu <sup>2+</sup> | Ni <sup>2+</sup> |
| (i) Citrate added to metal solution in 1:2 (metal: citrate molal ratio) | 30 mts.     | 41.0                                 | 120.0            | 125.0            | 40.0                                | 123.0            | 130.0            |
| (ii) do.  | 1 hour      | 45.0                                 | 110.0            | 130.0            | 40.0                                | 123.0            | 130.0            |
| (iii) Tartrate added to metal solution                                  | 1 hour      | 70.0                                 | 215.0            | 234.0            | 81.0                                | 246.0            | 260.0            |

agents to the metal salt solutions. The most significant result is obtained when twice the excess of the citrate is added to the metal salt solution ( $R_F$  values Zn<sup>2+</sup> = 1.0; Cu<sup>2+</sup> = 0.69; Ni<sup>2+</sup> = 0.09). Good results are also obtained when tartrate is added ( $R_F$  values Zn<sup>2+</sup> = 0.96; Cu<sup>2+</sup> = 0.54; Ni<sup>2+</sup> = 0.08) to the metal solutions.

**Quantitative Separation and Estimation of Ni<sup>2+</sup>, Cu<sup>2+</sup> and Zn<sup>2+</sup>.**—Two chromatograms were run under similar conditions. One of these chromatograms was developed and the position of the spots located. The undeveloped chromatograms were cut into three portions depending on the position of individual components which were then extracted from the filter paper into solution and estimated spectrophotometrically.

**Cu<sup>2+</sup> :** Copper at pH 8.5 (in presence of citric acid) was extracted with lead diethyl dithiocarbamate in chloroform and the absorbance noted at 560 nm.

**Ni<sup>2+</sup> :** Pink complex of Ni(DMG)<sub>2</sub> was extracted in chloroform at pH 7.5 and the absorbance noted at 420 nm.

**Zn<sup>2+</sup> :** Estimated using xylenol orange at pH 6.3 (acetic acid, sodium acetate buffer) and absorbance was noted at 570 nm.

The absorbance of unknown solution is compared from the calibration curve obtained from standard known solutions under similar conditions. Some of the results are summarized in Table I.

Thanks are due to Prof. R. H. Sabasrabudhey for providing facilities.

## DETECTION OF PYROGALLOL WITH CACOTHELINE

MENTION may be made of the reagents like HCHO-HCl<sup>1</sup> and tetramethyl aminobenzophenone<sup>2</sup> for the sensitive detection of pyrogallol. In this communication the details of the detection of pyrogallol with cacotheline are given. The present method is simple, comparatively more selective and sensitive over the other methods.

**Experimental procedure.**—0.4 ml of conc. sulphuric acid (AR) is mixed with 0.05 ml of 0.005% cacotheline and 0.05 ml of test solution. A stable pink colour is produced indicating the presence of pyrogallol (limit of identification: 25  $\mu\text{g}$  ml). The sensitivity is nearly doubled by increasing the temperature to 70° C. It is found that phenol, hydroquinone, *m*-cresol, *p*-cresol, pyrocatechol, 1-naphthol, 2-naphthol, gallic acid, phloroglucinol and hydroxyhydroquinone will not interfere in 3 fold excess. Resorcinol and *o*-cresol will interfere because of the brown colour.

The pink compound was found to be the reduced product of cacotheline as given below and the spectrum exhibits maximum absorption in the region of 525-530 nm<sup>3</sup>.

### ESTIMATION OF OXALATE IONS AND OXALIC ACID USING EDTA

The estimation of the oxalate anion and oxalic acid by the EDTA method involves the quantitative precipitation of the oxalate by adding a known excess of standard lead acetate solution and back titrating the excess lead acetate with EDTA. The method is simple and accurate. The precipitation merely involves mixing the cold solutions and the easily filterable precipitate shows practically no creep.

**Discussion.**—The method adopted is the converse of the usual method for the estimation of lead<sup>2+</sup>. It is found that under the conditions of precipitation with excess of lead acetate, oxalic acid and oxalate are both quantitatively precipitated and no distinction in practical procedure is called for. The results both in the case of oxalic acid and oxalate show practically the same accuracy, ~ 0.5%. The presence of small quantities of oxidisable impurities might pose a serious problem in the case of permanganimetry, whereas the accuracy of EDTA method is not affected by such impurities.
